Essential Med Notes

Comprehensive medical reference and review for the
United States Medical Licensing Exam Step 2 and
the Medical Council of Canada Qualifying Exam Part I

31st Edition

Editors-in-Chief:
Justin Hall and Azra Premji

Wherever the art of medicine is loved,
there is also a love of humanity.

– Hippocrates
**Note:**

Many of you have wondered about the *Toronto Notes* logo, which is based on the rod of Asclepius, the Greek god of medicine. The rod of Asclepius consists of a single serpent entwined around a staff. This icon symbolizes both rebirth, by way of a snake shedding its skin, and also authority, by way of the staff.

In ancient Greek mythology, Asclepius was the son of Apollo and a skilled practitioner of medicine who learned the medical arts from the centaur Chiron. Asclepius’ healing abilities were so great that he was said to be able to bring back people from the dead. These powers displeased the gods, who punished Asclepius by placing him in the sky as the constellation Orphiuchus.

The rod of Asclepius is at times confused with the caduceus, or wand, of Hermes, a staff entwined with two serpents and often depicted with wings. The caduceus is often used as a symbol of medicine or medical professionals, but there is little historical basis for this symbolism.

As you may have guessed, our logo uses the rod of Asclepius that is modified to also resemble the CN Tower – our way of recognizing the university and community in which we have been privileged to learn the art and science of medicine.

Thomas O’Brien, MD
Class of 2009
M.D. Program, University of Toronto
Dear Readers,

As Editors-in-Chief of Essential Med Notes 2015, we are proud to present the current edition.

First produced in 1985 from a set of study notes drafted by medical students at the University of Toronto, Toronto Notes and its international version, Essential Med Notes, have grown to be one of the premier study resources for generations of medical graduates in Canada and abroad. This rich history is rooted in our commitment to publish a student-edited, comprehensive study resource to serve students across clinical rotations and in preparation for the USMLE Step 2 and the Canadian MCCQE Part I.

For 30 years, we have remained committed to our original vision. With each successive edition, we strive to enhance the features of our print and online resources by listening to the feedback of our users. The focus of Essential Med Notes 2015 is to make medical knowledge accessible and retainable by distilling information into high-quality figures, tables, algorithms, and clinical pearls. This edition of Essential Med Notes offers new and exciting changes. We feature a consistent and easy-to-view layout across 30 chapters including the new Vascular Surgery chapter. Moreover, we have updated the text to reflect current best practice guidelines and clinically-relevant advances in medical research. As well, the text has been revised to reflect the new DSM-5 clinical guidelines. We are particularly excited to present the new accompanying Essential Med Notes Handbook. In response to user feedback, the Handbook has been streamlined to provide you with the most essential and up-to-date information on clinical scenarios commonly encountered while on the ward, in the clinic, or in the operating room. Finally, we have enhanced the Essential Med Notes eBook to include additional high-quality color images for a superior mobile learning experience.

Essential Med Notes 2015 is produced by Toronto Notes for Medical Students Inc., a non-profit organization supporting various medical student initiatives including community outreach programs and medical school clubs through the University of Toronto Medical Society, charitable events, and student bursaries and scholarships.

The production of this text would not have been possible without the commitment, energy, and passion of our dedicated team of over 150 students, artists, and faculty members at the University of Toronto's Faculty of Medicine as well as numerous faculty members at top-ranked U.S. institutions. We are grateful for the dedication and significant contributions of our lead editors: Amin Bahubeshi, Jillian Bardsley, Mandeep Pinky Gaidhu, Amanda Huynh, Jessica Huynh, Vahagn Karapetyan, Evan Lilly, Khaled Ramadan, and Karim Virani. We would also like to thank our Production Managers, Charles He and Ilya Mukovozov, for their hard work and efforts toward making this year’s edition a success. Our website team has been invaluable in improving our online resources to offer our users an enhanced electronic experience. We appreciate the creativity put forth by the Biomedical Communications artists in conceptualizing and developing numerous new illustrations as well as the innovative three-dimensional cover rendering. We would also like to acknowledge our partners at Type & Graphics, particularly Enrica Aguilera, for their continued guidance in the production of this text. Finally we would like to express our deepest gratitude to all previous Editors-in-Chief of Essential Med Notes.

We hope you find Essential Med Notes to be an indispensable resource. We encourage your feedback and place tremendous importance on making changes based on the user experience. On behalf of the 2015 editorial team, we wish you the best in your studies and hope that you will find Essential Med Notes 2015 a valuable asset to your success.

Sincerely,

Justin Hall, MSc, MPH and Azra Premji, MSc, RRT
Editors-in-Chief, Essential Med Notes 2015
MD Program, University of Toronto
Acknowledgements

We would like to acknowledge the exceptional work of all previous *Essential Med Notes* and *Toronto Notes* (formerly MCCQE Notes) Editors-in-Chief and their editorial teams. The 2015 edition of this text was made possible with their contributions.

How to Use This Book

This book has been designed to remain as one book or to be taken apart into smaller booklets. Identify the beginning and end of a particular section, then carefully bend the pages along the perforated line next to the spine of the book. Then tear the pages out along the perforation.

The layout of *Essential Med Notes 2015* allows easy identification of important information. These items are indicated by icons interspersed throughout the text:

<table>
<thead>
<tr>
<th>Icon</th>
<th>Icon Name</th>
<th>Significance</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image" alt="Key Objectives" /></td>
<td>Key Objectives</td>
<td>This icon is found next to headings in the text. It identifies key objectives and conditions as determined by the Medical Council of Canada or the National Board of Medical Examiners in the USA. If it appears beside a dark title bar, all subsequent subheadings should be considered key topics.</td>
</tr>
<tr>
<td><img src="image" alt="Clinical Pearl" /></td>
<td>Clinical Pearl</td>
<td>This icon is found in sidebars of the text. It identifies concise, important information which will aid in the diagnosis or management of conditions discussed in the accompanying text.</td>

Chapter Divisions

To aid in studying and finding relevant material quickly, each chapter is organized in the following general framework:

**Basic Anatomy/Physiology Review**
- features the high-yield, salient background information students are often assumed to have remembered from their early medical school education

**Common Differential Diagnoses**
- aims to outline a clinically useful framework to tackle the common presentations and problems faced in the area of expertise

**Diagnoses**
- the bulk of the book
- etiology, epidemiology, pathophysiology, clinical features, investigations, management, complications, and prognosis

**Common Medications**
- a quick reference section for review of medications commonly prescribed
## Common Unit Conversions

### Temperature Conversions

- **Celsius** → **Fahrenheit** \( F = (C \times 1.8) + 32 \)
- **Fahrenheit** → **Celsius** \( C = (F - 32) \times 0.5555 \)

### Weight Conversions

- **Kilograms** → **Pounds** 1 kg = 2.2 lbs
- **Pounds** → **Ounces** 1 lb = 16 oz
- **Ounces** → **Grams** 1 oz = 28.3 g
- **Inches** → **Centimetres** 1 in = 2.54 cm

American law applicable to medical practice varies between state jurisdictions and changes over time. Criminal law is nationwide, but non-criminal (civil) law varies between states. This section is meant to serve only as a guide. Students and physicians should ensure that their practices conform to local and current laws.
The US Health Care System

Overview of US Health Care System

• the United States health care system is primarily market-based
• it is funded and delivered by a mixture of the public, private, and voluntary sectors; private-for-profit is the prevailing method of delivery
• public funding is derived from taxes raised at both the federal and state government levels

History

1901  American Medical Association established as the national organization of state and local medical groups

1929  Baylor Plan developed
• created by Dr. Justin Ford Kimball to ensure that teachers could pay their medical bills
• teachers pay 50 cents/mo in exchange for guarantee of medical services for 21 d

1930s  more hospitals adopt medical insurance plans as per the Baylor Plan

1939  Community hospitals work together to create health-care plans
• American Hospital Association (AHA) uses the term "Blue Cross" to describe health care plans that meet their standards
• emergence of prepaid plans covering physician and surgeon services

1946  Blue Shield created and represents physician sponsored health-care plans, which became the official designation for AHA health care plans in 1960

1954  Social Security coverage begins to include disability benefits

1965  Medicare and Medicaid programs introduced government funded health-care plans

1970s/1980s  • emergence of Health Maintenance Organizations (HMOs)
• HMOs offer managed care plans: health care packages that are provided by an HMO approved network of health care providers

1993  Universal health care system proposed but rejected by Congress

1996  Mental Health Parity Act passed
• invoked to decrease discrimination in health care coverage for mental health illnesses
• aggregate annual and lifetime limits for mental health services must match aggregate annual and lifetime limits for medical and surgical services

1996  Health Insurance Portability and Accountability Act passed
• Title 1: Health Care Access, Portability, and Renewability
  • provides protection of health care coverage to employees and their families if they change or lose their job
• Title 2: Preventing Health Care Fraud and Abuse; Administrative Simplification; Medical Liability Reform
  • addresses and establishes national standards for electronic health care transactions and security and privacy of health data

1997  State Children's Health Insurance Program (SCHIP) created
• states extend health coverage to uninsured children

1999  Ticket to Work and Work Incentives Improvement Act
• enables people with disabilities to be employed without affecting their Medicaid or Medicare coverage

2010  Affordable Care Act
• reform to health care to improve access to affordable health coverage and creates regulations on activities of private health insurance providers
Health Care Reform

- **Patient Protection and Affordable Care Act** and the **Health Care and Education Reconciliation Act** of 2010 are federal statutes signed into law in March 2010 that include a number of new health care provisions to be implemented over 8 yr:
  - expand Medicaid eligibility, provide subsidies for insurance premiums and incentives for businesses to provide health care benefits, prohibit denial of coverage/claims for pre-existing conditions, and establish health-insurance exchanges
  - costs are offset by a number of health care related taxes, including a tax penalty for citizens with no health insurance (low income persons and persons from a recognized religious sect are exempt)

Health Care Expenditure and Delivery in the US

- health care in the US represents a large economic sector
  - health care comprises over 17.9% of the gross domestic product (GDP) (highest in the OECD), amounting to $8,608 USD per capita in 2011
  - one advantage is the widespread availability of technology – the US has 4 times as many MRI machines per capita than Canada
- the US scores poorly on some indicators of population health, with a life expectancy below the OECD average and infant mortality above the OECD average; possible factors that account for this discrepancy are:
  - poor health of large uninsured population
  - high cost of health care administration
  - the provision of inefficient high-cost, high-intensity care
  - the higher-spending regions in the US do not provide any better quality of care, access to care, health outcomes, or satisfaction with care when compared to the lower-spending regions
- the US has the highest level of obesity of all OECD nations at 34.3%; this has major implications for future health care spending

Health Care Funding

- over 60% of healthcare provisions and spending come from universal programs such as Medicare, Medicaid, TRICARE, the Children's Health Insurance Program, and the Veterans Health Administration
- based on the total expenditure on health care, 31% goes to hospital care, 21% goes to physicians/clinical services, 10% to pharmaceuticals, 4% to dental, 6% to nursing homes, 3% to home health care, 3% for other retail products, 3% for government public health activities, 7% to administrative costs, 7% to investment, and 6% to other professional services

Health Care Delivery

- health care facilities are largely operated by the private sector
- it is estimated that approximately 62% of hospitals are non-profit, 20% are government owned, and 18% are for-profit

Access to Health Services

- 70% of Americans under the age of 65 have private health insurance, either employer-sponsored or individually purchased; 12% receive health care through public health insurance; 18%, mainly the poor, have no health insurance
- access to publicly funded health services occurs primarily through two programs, Medicare and Medicaid, which were created by the 1965 Social Security Act
- other federal government-funded health programs include the Military Health Services System, the Veterans Affairs Health Services System, the Indian Health Service, and the Prison Health Service

Ethical and Legal Issues in Medicine

Introduction to the Principles of Ethics

- ethics addresses
  1) principles and values that help define what is morally right and wrong
  2) rights, duties, and obligations of individuals and groups
- The practice of medicine assumes there is one code of professional ethics for all doctors and that they will be held accountable by that code and its implications

Table 2. The Four Principles of Medical Ethics

<table>
<thead>
<tr>
<th>Principle</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Autonomy</td>
<td>Recognizes an individual’s right and ability to decide for himself/herself according to his/her beliefs and values</td>
</tr>
<tr>
<td></td>
<td>Not applicable in situations where informed consent and choice are not possible or may not be appropriate</td>
</tr>
<tr>
<td>Beneficence</td>
<td>The patient-based ‘best interests’ standard that combines doing good, avoiding harm, taking into account the patient’s values, beliefs, and preferences (so far as these are known)</td>
</tr>
<tr>
<td></td>
<td>Autonomy should be integrated with the physician’s conception of a patient’s medically-defined best interests</td>
</tr>
<tr>
<td></td>
<td>The aim is to minimize harmful outcomes and maximize beneficial ones</td>
</tr>
<tr>
<td></td>
<td>Paramount in situations where consent/choice is not possible or may not be appropriate</td>
</tr>
<tr>
<td>Non-Maleficence</td>
<td>Obligation to avoid causing harm; primum non nocere (“First, do no harm”)</td>
</tr>
<tr>
<td></td>
<td>A limit condition of the Beneficence principle</td>
</tr>
<tr>
<td>Justice</td>
<td>Fair distribution of benefits and harms within a community</td>
</tr>
<tr>
<td></td>
<td>Concept of fairness: Is the patient receiving what he/she deserves – his/her fair share? Is he/she treated the same as equally situated patients? How do one set of treatment decisions impact on others?</td>
</tr>
<tr>
<td></td>
<td>Respects basic human rights, such as freedom from persecution and the right to have one’s interests considered and respected</td>
</tr>
</tbody>
</table>

- the AMA has a Code of Medical Ethics
  - articulates the values of medicine as a profession and defines medicine’s integrity
  - source of the profession’s authority to self-regulate
  - evolving document that changes as new questions arise; AMA policy positions (“AMA Policy”) address current health care issues, the health care system, internal organizational structure, decision-making processes, and medical science and technology

Confidentiality

Overview of Confidentiality

- a full and open exchange of information between patient and physician is central to a therapeutic relationship
- privacy is the right of patients (which they may forego) while confidentiality is the duty of doctors (which they must respect barring patient consent or the requirements of the law)
• if inappropriately breached by a doctor, he/she can be sanctioned by the hospital, court, or regulatory authority
• based on the ethical principle of patient autonomy, patients have the right to the following:
  ▪ control of their own information
  ▪ the expectation that information concerning them will receive proper protection from unauthorized access by others (see Privacy of Medical Records)
  ▪ confidentiality may be ethically and legally breached in certain circumstances (i.e. the threat of harm to others)
  ▪ unlike the solicitor-client privilege, there is no ‘physician-patient privilege’ by which a physician, even a psychiatrist, can promise the patient absolute confidentiality
  ▪ physicians failing to abide by such regulations could be subject to professional or civil actions

Statutory Reporting Obligations
• legislation has defined specific instances where public interest overrides the patient right to confidentiality. These vary by state, but often include the following:
  1. suspected child or elder abuse or neglect – report to local child welfare authorities
  2. fitness to drive a vehicle or fly an airplane – report to Department of Motor Vehicles
  3. communicable diseases – report to public health authority and identifiable people at risk
  4. improper conduct of other physicians or health professionals – report to college or regulatory body of the health professional
  5. gunshot and knife wounds – notify police
  6. vital statistics must be reported; reporting varies by jurisdiction
• physicians who fail to report in these situations in the manner prescribed by state jurisdiction are subject to prosecution and penalty, and may be liable if a third party has been harmed

Duty to Protect/Warn
• the physician has a duty to protect the public from a known (or potential) dangerous patient; this may involve taking appropriate clinical action (e.g. involuntary detainment of violent patients for clinical assessment), informing the police, or warning the potential victim(s) if a patient expresses an intention to harm
• first established by a Supreme Court of California decision in 1976; known as the Tarasoff decision
• concerns of breaching confidentiality should not prevent the MD from exercising the duty to protect; however, the disclosed information should not exceed that required to protect others
• applies in a situation where:
  1. there is a clear risk to identifiable person(s);
  2. there is a risk of serious bodily harm or death; and
  3. the danger is imminent (i.e. more likely to occur than not)

Disclosure for Legal Proceedings
• disclosure of health records can be compelled by a court order, warrant, or subpoena

Privacy of Medical Records
• privacy of health information is protected by professional codes of ethics, legislation, and the physician’s fiduciary duty
• the legal duties of physicians involving patient confidentiality of medical records are outlined in the Health Insurance Portability and Accountability Act (HIPPA), which establishes principles for the collection, use, and disclosure of information that is part of commercial activity (i.e. physician practices, pharmacies, private labs)
• other aspects involving confidentiality are governed by state policy

Duties of Physicians with Regards to the Privacy of Health Information
• inform patients of information-handling practices through various means (i.e. posting notices, brochures and pamphlets, and/or through discussions with patients)
• obtain the patient’s expressed consent to disclose information to third parties
• provide the patient with access to their entire medical record; exceptions include instances where there is potential for serious harm to the patient or a third party
• provide secure storage of information and implement measures to limit access to patient records
• ensure proper destruction of information that is no longer necessary

Consent and Capacity

Ethical Principles Underlying Consent and Capacity
• consent is the autonomous authorization of a medical intervention by a patient
• usually, the principle of respect for patient autonomy overrides the principle of beneficence
• where a patient cannot make an autonomous decision (i.e. incapable), it is the duty of the SDM (or the physician in an emergency) to act on the patient’s known prior wishes or, failing that, to act in the patient’s best interests
• there is a duty to discover, if possible, what the patient would have wanted when capable
• central to determining best interests is understanding the patient's values, beliefs, and cultural or religious background
• more recently expressed wishes take priority over remote ones
• patient wishes may be verbal or written
• patients found incapable to make a specific decision should still be involved in that decision as much as possible
• agreement or disagreement with medical advice does not determine findings of capacity/incapacity
• however, patients opting for care that puts them at risk of serious harm that most people would want to avoid should have their capacity carefully assessed

Four Basic Requirements of Valid Consent
1. Voluntary
   - consent must be given free of coercion or pressure (i.e. from parents or other family members who might exert 'undue influence')
   - the physician must not deliberately mislead the patient about the proposed treatment
2. Capable
   - the patient must be able to understand and appreciate the nature and effect of the proposed treatment
3. Specific
   - the consent provided is specific to the procedure being proposed and to the provider who will carry out the procedure (i.e. the patient must be informed if students will be involved in providing the treatment)
4. Informed
   - sufficient information and time must be provided to allow the patient to make choices in accordance with their wishes; information should include:
     • the nature of the treatment or investigation proposed and its expected effects
     • all significant risks and special or unusual risks
     • alternative treatments or investigations and their anticipated effects and significant risks
     • the consequences of declining treatment
     • risks that are common sense need not be disclosed (i.e. bruising after venipuncture)
     • answers to any questions the patient may have
     • the reasonable person test – the physician must provide all information that would be needed "by a reasonable person in the patient's position" to be able to make a decision
     • disclose common adverse events (>1/200 chance of occurrence) and serious risks (e.g. death) even if remote
     • it is the physician's responsibility to make reasonable attempts to ensure that the patient understands the information
     • physicians should not withhold information about a legitimate therapeutic option based on personal conscience (i.e. not discussing the option of emergency contraception)

Obtaining Legal Consent
• consent of the patient must be obtained before any medical intervention is provided; consent can be:
  • verbal or written, although written is usually preferred
    • a signed consent form is only evidence of consent – it does not replace the process for obtaining valid consent
    • what matters is what the patient understands and appreciates, not what the signed consent form states
  • implied (e.g. a patient holding out their arm for an immunization) or expressed
• consent is an ongoing process and can be withdrawn or changed after it is given, unless stopping a procedure would put the patient at risk of serious harm

Exceptions to Consent
1. Emergencies
   • treatment can be provided without consent where a patient is experiencing severe suffering, or where a delay in treatment would lead to serious harm or death and consent cannot be obtained from the patient or their surrogate decision-maker (SDM)
   • emergency treatment should not violate a prior expressed wish of the patient (i.e. a signed Jehovah's Witness card)
   • if patient is incapable, MD must document reasons for incapacity and why situation is emergent
   • patients have a right to challenge a finding of incapacity as it removes their decision-making ability
   • if a SDM is not available, MD can treat without consent until the SDM is available or the situation is no longer emergent

Major Exceptions to Consent
• Emergencies
• Communicable diseases
• Mental health legislation
2. Legislation
- mental health legislation allowing for involuntary commitment is state governed. In general, an individual may be detained if he/she poses a threat to the self or others
- public health legislation allows medical officers of health to detain, examine, and treat patients without their consent (e.g. a patient with TB refusing to take medication) to prevent transmission of communicable diseases (see Population Health and Epidemiology, PH19)

3. Special Situations
- public health emergencies (i.e. an epidemic or communicable disease treatment)
- warrant for information by police

Consequences of Failure to Obtain Valid Consent
- treatment without consent is battery (an offense in tort), even if the treatment is life-saving (excluding situations outlined in exceptions section above)
- treatment of a patient on the basis of poorly informed consent may constitute negligence, also an offense in tort
- the onus of proof that valid consent was not obtained rests with the plaintiff (usually the patient)

Consent
- treatment without consent = battery, including if NO consent or if WRONG procedure
- treatment with poor or invalid consent = negligence

Overview of Capacity
- capacity is the ability to
  - understand information relevant to a treatment decision
  - appreciate the reasonably foreseeable consequences of a decision or lack of a decision
- capacity is specific for each decision (i.e. a person may be capable to consent to having a chest x-ray, but not for a bronchoscopy)
- capacity can change over time (i.e. temporary incapacity secondary to delirium)
- a person is presumed capable unless there is good evidence to the contrary
- capable patients are entitled to make their own decisions
- capable patients can refuse treatment even if it leads to serious harm or death; however, decisions that put patients at risk of serious harm or death require careful scrutiny

Assessment of Capacity
- capacity assessments must be conducted by a physician and, if appropriate, in consultation with other health care professionals (e.g. another physician, a mental health nurse)
- clinical capacity assessment may include:
  - specific capacity assessment (i.e. capacity specific to the decision at hand)
    1. effective disclosure of information and evaluation of patient's reason for decision
    2. understanding of:
      - his/her condition
      - the nature of the proposed treatment
      - alternatives to the treatment
      - the consequences of accepting and rejecting the treatment
      - the risks and benefits of the various options
    3. for the appreciation needed for decision making capacity, a person must:
      - acknowledge the condition that affects him/herself
      - be able to assess how the various options would affect him or her
      - be able to reach a decision and adhere to it, and make a choice, not based primarily upon delusional belief (test: are their beliefs responsive to evidence?)
  - general impressions
  - input from psychiatrists, neurologists, etc.
- employ "Aid to Capacity Evaluation"
  - a decision of incapacity may warrant further assessment by psychiatrist(s) or the courts

Table 3. Aid to Capacity Evaluation

| Ability to understand the medical problem |
| Ability to understand the proposed treatment |
| Ability to understand the alternatives (if any) to the proposed treatment |
| Ability to understand the option of refusing treatment or of it being withheld or withdrawn |
| Ability to appreciate the reasonably foreseeable consequences of accepting the proposed treatment |
| Ability to appreciate the reasonably foreseeable consequences of refusing the proposed treatment |
| Ability to make a decision that is not substantially based on delusions or depression |

Adapted from Elchels E, et al. CMAJ 1996;155:657-661
Treatment of the Incapable Patient in a Non-Emergent Situation

- obtain informed consent from SDM
- criteria for detaining a patient against his/her will to receive treatment are state specific. In most circumstances, the physician must:
  - document assessment by psychiatrist or other qualified agent in chart
  - notify patient and agent verbally or in writing of assessment
  - if the patient objects to the determination, healthcare professionals cannot override the patient's wishes without obtaining a court order

Surrogate Decision-Makers (SDM)

- SDM are appointed if no living will or POA exists and must follow the following principles when giving informed consent:
  - act in accordance with wishes previously expressed by the patient while capable
  - if wishes unknown, act in the patient's best interest, taking the following into account:
    1. values and beliefs held by the patient while capable
    2. whether well-being is likely to improve with vs. without treatment
    3. whether the expected benefit outweighs the risk of harm
    4. whether a less intrusive treatment would be as beneficial as the one proposed
- the final decision of the SDM may and should be challenged by the MD if the MD believes the SDM is not abiding by the above principles

INSTRUCTIONAL ADVANCE DIRECTIVES

- allow patients to exert control over their care once they are no longer capable
- the patient sets out their decisions about future health care, including who they would allow to make treatment decisions on their behalf and what types of interventions they would want
- takes effect once the patient is incapable with respect to treatment decisions
- patients should be encouraged to review these documents with their family and physicians and to reevaluate them often to ensure they are current with their wishes

Powers of Attorney

- all Guardians and Attorneys have fiduciary duties for the dependent person

Definitions

- Power of Attorney for Personal Care
  - a legal document in which one person gives another the authority to make personal care decisions (health care, nutrition, shelter, clothing, hygiene, safety) on their behalf if they become mentally incapable
- Guardian of the Person
  - someone who is appointed by the Court to make decisions on behalf of an incapable person in some or all areas of personal care, in the absence of a POA for personal care
- Continuing Power of Attorney for Property
  - a legal document in which a person gives another the legal authority to make decisions about their finances if they become unable to make those decisions
- Guardian of Property
  - someone who is appointed by the Public Guardian and Trustee or the Courts to look after an incapable person's property or finances
- Public Guardian and Trustee
  - acts as a SDM of last resort on behalf of mentally incapable people who do not have another individual to act on their behalf
- Pediatric Aspects of Capacity
  - age of consent is state specific
  - physicians treating pediatric patients generally must obtain informed consent from a parent or a legal guardian
  - emancipated or mature minors may provide consent to their own medical care
  - infants and children are assumed to lack mature decision-making capacity for consent but they should still be involved (i.e. be provided with information appropriate to their comprehension level)
  - adolescents are usually treated as adults
  - preferably, assent should still be obtained from patient, even if not capable of giving consent
  - in the event that the physician believes the SDM is not acting in the child's best interest, an appeal must be made to the local child welfare authorities
  - under normal circumstances, parents have right of access to the child's medical record

When disagreements occur, institutional policies for timely conflict resolution should be followed, and may be followed by consultation with an ethics committee, pastoral service, or other counseling resource; resolution of disagreements in the courts should be pursued only as a last resort.
Negligence

**Ethical Basis**
- the doctor-patient relationship is formed on trust, which is recognized in the concept of fiduciary duty/responsibility of physician towards patient
- negligence or malpractice is a form of failure on the part of the physician in fulfilling his/her fiduciary duty in providing appropriate care and leading to harm of the patient (and/or abuse of patient's trust)

**Legal Basis**
- physicians are legally liable to their patients for causing harm (tort) through a failure to meet the standard of care applicable under the circumstances
- standard/duty of care is defined as one that would reasonably be expected under similar circumstances of an ordinary, prudent physician of the same training, experience, specialization, and standing
- liability arises from physician's common law duty of care to his/her patients in the doctor/patient relationship
- action(s) in negligence (or civil liability) against a physician must be launched by a patient within a specific prescribed period required by the respective state in which the actions occurred

Truth-Telling

**Ethical Basis**
- helps to promote and maintain a trusting physician-patient relationship
- patients have a right to be told important information that physicians have regarding their care
- enables patients to make informed decisions about health care and their lives

**Legal Basis**
- required for valid patient consent (see Consent and Capacity, ELOAM5)
  - goal is to disclose information that a reasonable person in the patient's position would need in order to make an informed decision ("standard of disclosure")
- withholding information can be a breach of fiduciary duty and duty of care
- obtaining consent by using misleading information can be seen as negligent

**Evidence about Truth-Telling**
- most patients want to know what is wrong with them
- although many patients want to protect family members from bad news, they themselves would want to be informed in the same situation
- truth-telling improves compliance and health outcomes
- informed patients are more satisfied with their care
- negative consequences of truth-telling can include decreased emotional well-being, anxiety, worry, social stigmatization, and loss of insurability

**Challenges in Truth-Telling**

**Medical Error**
- medical error may be defined as 'preventable adverse events' caused by the patient's medical care and not the patient's underlying illness. Some errors may be identified before they harm the patient, so not all error is truly ‘adverse’
  - serious adverse events (i.e. those resulting in death, hospitalization, or medical or surgical intervention) must be reported to the Food and Drug Administration (FDA)
- many jurisdictions and professional associations expect and require physicians to disclose medical error; that is, any event that harms or threatens to harm patients must be disclosed to the patient or the patient's family and reported to the appropriate health authorities
- physicians should disclose to patients the occurrence of adverse events or errors caused by medical management, but should not suggest that they resulted from negligence because:
  - negligence is a legal determination
  - error is not equal to negligence
- disclosure allows the injured patient to seek appropriate corrective treatment promptly
  - physicians should avoid simple attributions as to cause and sole responsibility of others or oneself
  - physicians should offer apologies or empathic expressions of regret ("I wish things had turned out differently") as these can increase trust and are not admissions of guilt or liability

**Breaking Bad News**
- 'bad news' may be any information that reveals conditions or illnesses threatening the patient's sense of well-being
- caution patients in advance of serious tests about possible bad findings
• give warnings of impending bad news (see sidebar for example) and make sure you provide time for the patient
• poorly done disclosure may be as harmful as non-disclosure
• truth-telling may be a process requiring multiple visits
• adequate support should be provided along with the disclosure of difficult news
• SPIKES protocol was developed to facilitate “breaking bad news”

Arguments Against Truth-Telling
• may go against certain cultural norms and expectations
• may lead to patient harm and increased anxiety
• 10-20% of patients prefer not to be informed
• medical uncertainty may result in the disclosure of uncertain or inaccurate information

Exceptions to Truth-Telling
• patients may ‘waive’ the right to know: patient declines information that would normally be disclosed
• a patient may waive their right to know the truth about their situation when
  • the patient clearly declines to be informed
  • a strong cultural component exists that should be respected and acknowledged
  • the patient may wish others to be informed and make the medical decisions for him/her
  • the more weighty the consequences for the patient from non-disclosure, the more carefully one must consider the right to ignorance
• ‘Emergencies’: an urgent need to treat may legitimately delay full disclosure; the presumption is that most people would want such treatment and the appropriate SDM cannot be found
• ‘therapeutic privilege’
  • withholding information by the clinician in the belief that disclosure of the information would itself lead to severe anxiety, psychological distress, or physical harm to the patient
  • clinicians should avoid invoking therapeutic privilege due to its paternalistic overtones and is a defense of non-disclosure that is rarely accepted anymore
  • it is often not the truth that is unpalatable; it is how it is conveyed that can harm the patient

Ethical Issues in Health Care

Managing Controversial and Ethical Issues in Practice
• discuss in a non-judgmental manner
• ensure patients have full access to relevant and necessary information
• identify if certain options lie outside of your moral boundaries and refer to another physician if appropriate
• consult with appropriate ethics committees or boards
• protect freedom of moral choice for students or trainees

Reproductive Technologies

Overview of the Maternal-Fetal Relationship
• in general, maternal and fetal interests align
• in some situations, a conflict between maternal autonomy and the best interests of the fetus may arise

Ethical Issues and Arguments
• principle of reproductive freedom: women have the right to make their own reproductive choices
• coercion of a woman to accept efforts to promote fetal well-being is an unacceptable infringement of her personal autonomy

Legal Issues and Arguments
• the law upholds a woman’s right to life, liberty, and security of person and does not recognize fetal rights; key aspects of the mother’s rights include:
  • if a woman is competent and refuses medical advice, her decision must be respected even if the fetus will suffer
  • the fetus does not have legal rights until it is born alive and with complete delivery from the body of the woman
ART
- includes non-coital insemination, hormonal ovarian stimulation, and *in vitro* fertilization (IVF)
- topics with ethical concerns
  - donor anonymity vs. child-centered reproduction (i.e. knowledge about genetic medical history)
  - preimplantation genetic testing for diagnosis before pregnancy
  - use of new techniques without patients appreciating their experimental nature
  - access to ART
  - private vs. public funding of ART
  - social factors limiting access to ART (i.e. same-sex couples)
  - the 'commercialization' of reproduction

Fetal Tissue
- pluripotent stem cells can currently be derived from human embryonic and fetal tissue
- potential uses of stem cells in research
  - studying human development and factors that direct cell specialization
  - evaluating drugs for efficacy and safety in human models
  - cell therapy: using stem cells grown *in vitro* to repair or replace degenerated/destroyed/malignant tissues (e.g. Parkinson's disease)
  - genetic treatment aimed at altering somatic cells (i.e. myocardial or immunological cells) is acceptable and ongoing

ART: Ethically Appropriate Actions
- educate patients and address contributors to infertility (e.g. stress, alcohol, medications, etc.)
- investigate and treat underlying health problems causing infertility
- wait at least 1 yr before initiating treatment with ART (exceptions – advanced age or specific indicators of infertility)
- educate and prepare patients for potential negative outcomes of ART

Induced Abortion
- induced abortion: the active termination of a pregnancy before fetal viability
- fetal viability: fetus >500 g or >20 wk gestational age

Prenatal/Antenatal Genetic Testing
- uses
  - to confirm a clinical diagnosis
  - to detect genetic predisposition to a disease
  - allows preventative steps to be taken and helps patient prepare for the future
  - gives parents the option to terminate a pregnancy or begin early treatment

- ethical dilemmas arise because of the sensitive nature of genetic information. Important considerations of genetic testing include:
  - the individual and familial implications
  - its pertaining to future disease
  - its ability to identify disorders for which there are no effective treatments or preventive steps
  - its ability to identify the sex of the fetus

- ethical issues and arguments regarding the use of prenatal/antenatal genetic testing include:
  - obtaining informed consent is difficult due to the complexity of genetic information
  - doctor’s duty to maintain confidentiality vs. duty to warn family members
  - risk of social discrimination (e.g. insurance) and psychological harm

- legal aspects
  - testing requires informed consent
  - no standard of care exists for clinical genetics but physicians are legally obligated to inform patients that prenatal testing exists and is available
  - where a genetic defect is found in the fetus, prospective parents may request or refuse an abortion
  - a physician is required to alert prospective parents when a potential genetic problem exists

Genetic Testing: Ethically Appropriate Actions
- thorough discussion and realistic planning with patient before testing is done
- genetic counseling for delivery of complex information
End-of-Life Care

Overview of Palliative and End-of-Life Care
• focus of care is comfort and respect for person nearing death and maximizing quality of life for patient, family, and loved ones
• appropriate for any patient at any stage of a life-threatening illness
• may occur in a hospital, hospice, in the community, or at home
• often involves an interdisciplinary team of caregivers
• addresses the medical, psychosocial, and spiritual dimensions of care

Euthanasia and Physician-Assisted Suicide
• euthanasia: a deliberate act undertaken by one person with the intention of ending the life of another person to relieve that person’s suffering where the act is the cause of death
• physician-assisted suicide: the act of intentionally killing oneself with the assistance of a physician who deliberately provides the knowledge and/or the means

Common ethical arguments/opinions
• patient has right to make autonomous choices about the time and manner of own death
• belief that there is no ethical difference between the acts of euthanasia/assisted suicide and foregoing life-sustaining treatments
• belief that these acts benefit terminally ill patients by relieving suffering
• patient autonomy has limits
• death should be the consequence of the morally justified withdrawal of life-sustaining treatments only in cases where there is a fatal underlying condition, and it is the condition (not the withdrawal of treatment) that causes death

Legal aspects
• in the United States, euthanasia is considered an illegal act
• physician-assisted suicide is currently only legal in the state of Oregon

Acceptable use of palliative and end-of-life care
• the use of palliative sedation with opioids in end-of-life care, knowing that death may occur as an unintended consequence (principle of double effect) is distinguished from euthanasia and assisted suicide where death is the primary intent
• the appropriate withdrawal of life-support is distinguished from euthanasia and assisted suicide as it is seen as allowing the underlying disease to take its ‘natural course’
• refusals of care by the patient that may lead to death ought to be carefully explored by the physician to rule out any ‘reversible factors’ (poor palliation, depression, poverty, ill-education, isolation) that may be hindering authentic choice

Physician Responsibilities Regarding Death
• physicians are required by law to complete a medical certificate of death unless the coroner needs notification; failure to report death is a criminal offence
• coroner investigates these deaths, as well as deaths that occur in psychiatric institutions, jails, foster homes, nursing homes, hospitals to which a person was transferred from a facility, institution or home, etc.
• in consultation with forensic pathologists and other specialists, the coroner establishes:
  • the identity of the deceased
  • where and when the death occurred
  • the medical cause of death
  • the means of death (i.e. natural, accidental, suicide, homicide, or undetermined)
• coroners do not make decisions regarding criminality or legal responsibility
• in a number of jurisdictions, any death not certified by the person’s physician must be referred to the medical examiner

Physician Competence and Professionalism

Legal Considerations
• physicians’ conduct and competence are legally regulated to protect patients and society via mandatory membership to governing bodies
• physicians are legally required to maintain a license with the appropriate authority and are thus legally bound to outlined policies on matters of conduct within his/her medical practice

Common Policies on Physician Conduct
• physicians must ensure that patients have access to continuous on-call coverage and are never abandoned
• sexual conduct with patients, even when consented to by the patient, is a serious matter that can lead to accusations of battery by the patient and college. Important notes on this topic include:
  ▪ inappropriate sexual conduct includes intercourse, undue touching, references to sexual matters, sexual jokes, and physician presence when capable patients undress or dress
  ▪ in specified situations physicians may have a personal relationship with a patient provided a year has passed since the last therapeutic contact
  ▪ physicians are permanently prohibited from personal relationships with patients whom they saw for psychotherapy
  ▪ physicians must maintain adequate records for each patient, which include:
    ▪ demonstration that care has been continuous and comprehensive
    ▪ minimal standards for record-keeping, including diagnosis, differential diagnosis, appropriate tests and referrals, coherent patient record
    ▪ records storage for 10 years in most jurisdictions
    ▪ although the medical record is the property of the physician or an institution, the patient or the patient’s delegate must be allowed full access to information in the medical record upon (usually written) request
  ▪ in the hospital, physicians must ensure their own competence, respect hospital by-laws and regulations, practice only within the limits of granted privileges, cooperate with other hospital personnel, and maintain adequate hospital records

AMA Guidelines for Impaired, Incompetent, or Unethical Colleagues
• Impairment: it may be necessary to report an impaired physician who continues to practice despite reasonable offers of assistance and referral to a hospital or state physician health program. The duty to report under such circumstances may entail reporting to the licensing authority
• Incompetence: initial reports of incompetence should be made to the appropriate clinical authority who would be empowered to assess the potential impact on patient welfare and to facilitate remedial action. The hospital peer review body should be notified where appropriate. Incompetence that poses an immediate threat to the health and safety of patients should be reported directly to the state licensing board
• Unethical conduct: unethical conduct that violates state licensing provision should be reported to the state licensing board. It is appropriate to report unethical conduct that potentially violates criminal statues to law enforcement authorities

Research Ethics
• involves the systematic analysis of ethical dilemmas arising during research involving human subjects to ensure that:
  ▪ study participants are protected
  ▪ clinical research is conducted to serve the interests of the participants and/or society as a whole
  ▪ major ethical dilemmas arise when a physician’s obligation to the patient comes into conflict with other obligations and incentives
  ▪ any exceptions to disclosure for therapeutic consent do not apply in an experimental situation

Ethical Considerations for Research Involving Human Subjects
• patient’s participation in research should not put him/her at a known or probable disadvantage with respect to medical care
• participant’s voluntary and informed choice is usually required
• participants should have access to the treatment that is considered standard
• scientists must employ a scientifically valid design to answer the research question
• scientists must demonstrate sufficient value to justify the risk posed to participants
• research must be conducted honestly (i.e. carried out as stated in the approved protocol)
• patients must not be enticed into risky research by the lure of money and investigators must not trade the interests of patients for disproportionate recompense by a sponsor

Physician-Industry Relations
• health care delivery in the United States involves collaboration between physicians and the pharmaceutical and health supply industries in the areas of research, education, and clinical evaluation packages (i.e. product samples)
• physicians have a responsibility to ensure that their participation in such collaborative efforts is in keeping with their duties to their patients and society
• AMA Guidelines on the acceptance of gifts or free products from industry include:
  ▪ any gifts accepted by physicians should primarily entail a benefit to patients and should not be of substantial value (e.g. textbooks as they serve a genuine educational function)
- cash payments should not be accepted
- individual gifts on minimal value are acceptable as long as they are related to the physician’s work
- appropriate disclosure of financial support or conflict of interest should be made at conferences and/or meetings
- subsidies to underwrite costs of continuing education conference or meetings are acceptable
- payments to defray costs of a conference should not be accepted directly by the physician attending a conference
- no gifts should be accepted if there are strings attached

### Resource Allocation

**Definition:** the distribution of goods and services to programs and people

- physicians have the duty to inform patients about therapeutic options even if they are not available
- physicians must make health care resources available to patients in a manner which is fair and equitable, without bias or discrimination
  - need and benefit are morally relevant criteria for resource allocation
  - gender, sexual orientation, religion, level of education, or age alone are morally irrelevant criteria
- ethical dilemmas can arise when deciding how best to allocate resources. Common ethical dilemmas include:
  - fair chances vs. best outcome: best outcome generally favoured vs. giving all patients fair access to limited resources (e.g. transplant list prioritization)
  - priorities problem: how much priority should the sickest patients receive?
  - aggregation problem: modest benefits to many vs. significant benefits to few
  - democracy problem: when to rely on a fair democratic process to arrive at a decision

### Guidelines for Appropriately Allocating Resources

- the physician’s primary obligation is to
  - protect and promote the welfare and best interests of his or her patients
  - choose interventions known to be beneficial on the basis of evidence of effectiveness
  - seek the tests or treatments that will accomplish the diagnostic or therapeutic goal for the least cost
  - advocate for one’s patients but avoid manipulating the system to gain unfair advantage for them
  - resolve conflicting claims for scarce resources justly, on the basis of morally relevant criteria such as need and benefit, using fair and publicly defensible procedures
  - inform patients of the impact of cost constraints on care, but in a sensitive way
  - seek resolution of unacceptable shortages at the level of hospital management or government

### AMA Policy on Resource Allocation

- physicians have the "duty to do all that [they] can for the benefit of the individual patient"
- decisions regarding the allocation of limited resources among patients should consider ethically appropriate criteria, which includes:
  - likelihood of benefit
  - urgency of need
  - changes in quality of life
  - duration of benefit
  - the amount of resources required for successful treatment

### Professional Considerations

#### Elderly Patient
- identify their resuscitation options (CPR or DNR), if applicable
- check for documentation of advance directives and POA where applicable
- for further details see ELOAM8

#### Pediatric Patient
- identify the primary decision-maker (parents, guardian, wards-of-state, emancipated)
- be wary of custody issues if applicable

#### Terminally Ill or Palliative Patient
- consider the SPIKES approach to breaking bad news
- what are their goals of care, i.e. disease vs. symptom management?
- identify advance directives, POA, or SDM, if applicable
- check for documentation of resuscitation options (CPR or DNR) and likelihood of success
- for further details, see Geriatric Medicine, GM12
Incapable Patient
• if not already present, perform a formal capacity assessment
• identify if the patient has a SDM or who has their POA

Conscientious Objection

Patients Refusing Treatment
• in accordance with the principle of autonomy, it is acceptable for competent patients to refuse medical interventions for themselves or others; exceptions may occur
• if parents or SDMs make decisions that are clearly not in the “best interests” of an incapable child, thereby risking mortality or serious morbidity, physicians may seek a court order to provide treatment against parental wishes
• in emergent scenarios, physicians may initiate treatment on the basis of legal precedent if withholding treatment places child at serious health risk
• in lower risk scenarios, such as refusing childhood immunization in a developed nation, there is a stronger obligation to respect the autonomy of the decision-makers

Physicians Refusing to Provide Treatment
• physicians may refuse to provide treatment or discontinue relationships with patients, but must ensure these patients can access services elsewhere
• for example, a pediatrician who refuses to treat an unvaccinated child should refer the family to another practice. In this case, it is recommended the pediatrician continue working with the family in the hopes that further education might help parents to make more informed decisions regarding their child's health

Health Care Delivery

Important Acts/Charters
Affordable Health Care for America Act (House bill – H.R. 3962).
America’s Healthy Future Act (Baucus bill – S. 1798).
Patient Protection and Affordable Care Act, 2010 (PL 111-148).
Health Insurance Portability and Accountability Act (PL 104-191).
Overview of Anesthesia

- anesthesia: lack of sensation/perception
- approach to anesthesia
  1. pre-operative assessment
  2. patient optimization
  3. plan anesthetic
  4. post-operative care

  - various types of anesthesia
  - pre-medications
  - airway management
  - monitors
  - induction
  - maintenance
  - extubation

Pre-Operative Assessment

Purpose
- identify patient's medical and surgical issues
- arrange further investigations, consultations and treatments for patients not yet optimized
- plan and consent for anesthetic techniques

History and Physical

History
- age, gender
- indication for surgery
- surgical/anesthetic Hx: previous anesthetics, any complications, previous intubations, medications, drug allergies, post-operative N/V
- FHx: abnormal anesthetic reactions, malignant hyperthermia, pseudocholinesterase deficiency
- PMHx
  - CNS: seizures, TIA/strokes, raised ICP, spinal disease, aneurysm
  - CVS: angina/CAD, MI, CHF, HTN, valvular disease, dysrhythmias, peripheral vascular disease (PVD), conditions requiring endocarditis prophylaxis, exercise tolerance, CCS/ NYHA class (see Cardiology and Cardiac Surgery, C34 for NYHA classification)
  - respiratory: smoking, asthma, COPD, recent upper respiratory tract infection, sleep apnea
  - GI: GERD, liver disease, NPO status
  - renal: insufficiency, dialysis, chronic kidney disease
  - hematologic: anemia, coagulopathies, blood dyscrasias
  - MSK: conditions associated with difficult intubations – arthritides (e.g. rheumatoid arthritis), cervical tumors, cervical infections/abscesses, trauma to cervical spine, previous cervical spine surgery, Trisomy 21, scleroderma, conditions affecting neuromuscular junction (e.g. myasthenia gravis)
  - endocrine: diabetes, thyroid disorders, adrenal disorders
  - other: morbid obesity, pregnancy, ethanol/other drug use

Physical Exam
- weight, height, BP, pulse, respiratory rate
- focused physical exam of the CNS, CVS, and respiratory systems
- general assessment of nutrition, hydration, and mental status
- airway assessment
  - done to determine intubation difficulty (no single test is specific or sensitive)
  - cervical spine stability and neck movement – upper cervical spine extension, lower cervical spine flexion (“sniffing position”)
  - Mallampati classification
  - “3-2-1 rule”
    - thyromental distance (distance of lower mandible in midline from the mentum to the thyroid notch): <3 finger breadths (<6 cm) is associated with difficult intubation
    - mouth opening (<2 finger breadths is associated with difficult intubation)
    - anterior jaw subluxation (<1 finger breadh is associated with difficult intubation)
  - tongue size
  - dentition, dental appliances/prosthetic caps, existing chipped/loose teeth – must inform patients of rare possibility of damage
  - nasal passage patency (if planning nasotracheal intubation)
  - assess difficulty of ventilation
  - examination of anatomical sites relevant to lines and blocks
    - bony landmarks and suitability of anatomy for regional anesthesia (if relevant)
    - sites for IV, central venous pressure (CVP), and pulmonary artery (PA) catheters
Pre-Operative Investigations

- routine pre-operative investigations are only necessary if there are comorbidities, or certain indications

Table 1. Suggested Indications for Specific Investigations in the Pre-Operative Period

Impact of Anesthesia Management Characteristics on Severe Morbidity and Mortality
Anesth 2005;102:257-268
Study: Case-control study of patients undergoing anesthesia.
Patients: 807 cases and 883 controls were analyzed among a cohort of 869,483 patients undergoing anesthesia between 1995-1997. Cases were defined as patients who either remained comatose or died within 24 h of receiving anesthesia. Controls were defined as patients who neither remained comatose nor died within 24 h of receiving anesthesia.
Intervention: General, regional, or combined anesthesia to patients undergoing a surgical procedure.
Main Outcome: Coma or death within 24 h of receiving anesthesia.
Results: The incidence of 24 h post-operative death was 8.8 per 10,000 anesthetics (95% CI 8.2-9.5) and the incidence of coma was 0.5 (95% CI 0.3-0.8). Anesthesia management risk factors that were associated with a decreased risk of morbidity and mortality were equipment check with protocol and documentation, directly available anesthesiologist with no change during anesthesia, 2 persons present at emergence of anesthesia, reversal of muscle relaxation, and post-operative pain medication.

American Society of Anesthesiology Classification

- common classification of physical status at the time of surgery
- a gross predictor of overall outcome, NOT used as stratification for anesthetic risk (mortality rates)
- ASA 1: a healthy, fit patient
- ASA 2: a patient with mild systemic disease
  - e.g. controlled type 2 diabetes mellitus (DM), controlled essential HTN, obesity, smoker
- ASA 3: a patient with severe systemic disease that limits activity
  - e.g. stable CAD, COPD, DM, obesity
- ASA 4: a patient with incapacitating disease that is a constant threat to life
  - e.g. unstable CAD, renal failure, acute respiratory failure
- ASA 5: a moribund patient not expected to survive 24 h without surgery
  - e.g. ruptured abdominal aortic aneurysm (AAA), head trauma with increased ICP
- ASA 6: declared brain dead, a patient whose organs are being removed for donation purposes
- for emergency operations, add the letter E after classification (e.g. ASA 3E)
Pre-Operative Optimization

- in general, prior to elective surgery
  - any fluid and/or electrolyte imbalance should be corrected
  - extent of existing comorbidities should be understood and these conditions should be optimized prior to surgery
  - medications may need to be adjusted

Medications

- pay particular attention to cardiac and respiratory medications, opioids and drugs with many side effects and interactions

  - pre-operative medications to consider
    - prophylaxis
      - risk of GE reflux: sodium citrate 30 mL PO or ranitidine 150-300 mg PO or metoclopramide 10 mg PO 30 min to 1 h pre-operatively
      - risk of infective endocarditis, GI/GU interventions: antibiotics
      - risk of adrenal suppression: steroid coverage
      - anxiety; consider benzodiazepines
      - COPD, asthma: bronchodilators
    - CAD risk factors: nitroglycerin and β-blockers

  - pre-operative medications to stop
    - oral hypoglycemics: stop on morning of surgery
    - antidepressants: stop on morning of surgery
    - ACE inhibitors and angiotension receptor blockers: stop on morning of surgery
    - warfarin (consider bridging with heparin), anti-platelet agents (e.g. clopidogrel)
    - discuss perioperative use of ASA, NSAIDs with surgeon
    - in patients undergoing noncardiac surgery, starting or continuing low-dosing aspirin in the perioperative period does not appear to protect against post-operative MI or death, but increases the risk of major bleeding
      - Note: this does not apply to patients with bare metal stents or drug-eluting coronary stents
    - pre-operative medication to adjust
      - insulin (consider insulin/dextrose infusion or holding dose), prednisone, bronchodilators

Hypertension

- BP <180/110 is not an independent risk factor for perioperative cardiovascular complications
- target sBP <180 mmHg, dBP <110 mmHg
- assess for end-organ damage and treat accordingly

Coronary Artery Disease

- ACC/AHA Guidelines (2007) recommend postponing elective surgery 4-6 wk following an MI
  - this period carries an increased risk of reinfarction/death
- if operative procedure is essential and cannot be delayed, invasive intra- and post-operative ICU monitoring reduces the risk of reinfarction
- mortality with perioperative MI is 20-50%
  - may 4 cardiac events and mortality (controversial, as recent data suggests ↑ stroke risk)
  - continue β-blocker if patient is routinely taking it prior to surgery
  - consider initiation of β-blocker in:
    - patients with CAD or indication for β-blocker
    - intermediate risk surgery, especially vascular surgery

Endocrine Disorders

- diabetes mellitus
  - clarify type I vs. type II
  - assess glucose control with history and HbA1c; well controlled diabetics have more stable glucose levels intraoperatively
  - end organ damage: be aware of damage to CVS, renal, and nervous systems, including autonomic neuropathy
  - formulate intraoperative glucose management plan based on type (I vs. II), glucose control, and extent of end organ damage
• hyperthyroidism
  ▪ can experience sudden release of thyroid hormone (thyroid storm)
  ▪ treatment: β-blockers and pre-operative prophylaxis
• adrenocortical insufficiency (Addison's, exogenous steroid use)
  ▪ consider intraoperative steroid supplementation

Respiratory Diseases

• smoking
  ▪ adverse effects: altered mucus secretion and clearance, decreased small airway caliber, and altered immune response
  ▪ abstain at least 8 wk pre-op if possible
  ▪ if unable, abstaining even 24 h pre-operatively has shown benefit
• asthma
  ▪ pre-operative management depends on degree of baseline asthma control
  ▪ increased risk of bronchospasm from intubation, delivery of desflurane
    ▪ administration of short course (up to 1 wk) pre-operative corticosteroids and inhaled β2-agonists decreases the risk of bronchospasm and does not increase the risk of infection, delayed wound healing
    ▪ avoid non-selective β-blockers; cardioselective β-blockers (metoprolol, atenolol) do not increase risk of bronchospasm in the short-term
  ▪ delay elective surgery for poorly controlled asthma (increased cough or sputum production, active wheezing)
  ▪ delay elective surgery by a minimum of 6 wks if patient develops URTI
• COPD
  ▪ anesthesia, surgery and analgesia predispose the patient to atelectasis, bronchospasm, pneumonia, prolonged need for mechanical ventilation, and respiratory failure
  ▪ optimize with bronchodilators ± ICS ± antibiotics
  ▪ pre-operative ABG for all COPD stage II and III patients to assess baseline respiratory acidosis and plan post-operative management of hypercapnea
  ▪ cancel/delay elective surgery for acute exacerbation

Obesity and Obstructive Sleep Apnea

• assess for comorbid conditions in obese patient (independent risk factor for CVD, diabetes, OSA, cholelithiasis, HTN)
• previously undiagnosed conditions may require additional testing to characterize severity
• both obesity and OSA increase risk of difficult ventilation, intubation, and post-operative respiratory complications
  ▪ risk may be magnified with both diseases present

Hematological Disorders

• history of congenital or acquired conditions (sickle cell anemia, factor VIII deficiency, ITP, liver disease)
• evaluate hemoglobin, hematocrit and coagulation profiles when indicated (Table 1)
• anemia
  ▪ pre-operative treatments to increase hemoglobin (erythropoietin or pre-admission blood collection in certain populations)
• coagulopathies
  ▪ discontinue or modify anticoagulation therapies (warfarin, clopidogrel, ASA) in advance of elective surgeries
  ▪ administration of reversal agents if necessary: vitamin K, FFP, prothrombin complex concentrate, recombinant activated factor VII

Aspiration

• increased risk of aspiration with:
  ▪ decreased LOC
  ▪ trauma
  ▪ meals within 8 h
  ▪ suspected sphincter incompetence (GERD, hiatus hernia, nasogastric tube)
  ▪ increased abdominal pressure (pregnancy, obesity, bowel obstruction, acute abdomen)
  ▪ laryngeal mask vs. endotracheal tube (ETT)
• management
  ▪ reduce gastric volume and acidity
  ▪ delay inhibiting airway reflexes with muscular relaxants
  ▪ employ rapid sequence induction (see Rapid Sequence Induction, A16)

## Fasting Guidelines

### Fasting Guidelines Prior to Surgery (American Society of Anesthesiologists)
- 8 h after a meal that includes meat, fried or fatty foods
- 6 h after a light meal (such as toast or crackers) or after ingestion of infant formula or non-human milk
- 4 h after ingestion of breast milk
- 2 h after clear fluids (water, black coffee, tea, carbonated beverages, juice without pulp)

## Monitoring

### Guidelines to the Practice of Anesthesia and Patient Monitoring
- an anesthetist present: “the only indispensable monitor”
- a completed pre-anesthetic checklist: including ASA class, NPO policy, Hx and investigations
- a perioperative anesthetic record: HR and BP every 5 min, dose and route of drugs and fluids
- continuous monitoring: see Routine Monitors for All Cases

### Routine Monitors for All Cases
- pulse oximeter, apparatus to measure BP, electrocardiography, capnography and temperature monitoring are required for general anesthesia and sedation (Ramsey Sedation Scale 4-6), agent-specific anesthetic gas monitor when inhalational anesthetic agents are used
- the following must also be available: temperature probe, peripheral nerve stimulator, stethoscope, appropriate lighting, spirometer

### Elements to Monitor
- anesthetic depth
  ▪ inadequate: blink reflex present when eyelashes lightly touched, HTN, tachycardia, tearing or sweating
  ▪ excessive: hypotension, bradycardia
- oxygenation: pulse oximetry, fraction of inspired O₂ (FiO₂)
- ventilation: verify correct position of ETT, chest excursions, breath sounds, ETCO₂ analysis, monitor inhaled and exhaled concentrations of inhaled anesthetics
- circulation: pulse, heart sounds, BP, telemetry, oximetry, CVP, pulmonary capillary wedge pressure
- temperature

---

**Figure 2. Typical anesthesia monitor**

Pre-Anesthetic Checklist
SAMMM
Suction: connected and working
Airways: laryngoscope and blades, ETT, syringe, stylet, oral and nasal airways, tape, bag, and mask
Machine: connected, pressures okay, all meters functioning, vaporizers full
Monitors: available, connected, and working
Medications: IV fluids and kit ready, emergency medicines in correct location and accessible
**Airway Management**

### Airway Anatomy

- Resistance to airflow through nasal passages accounts for approximately 2/3 of total airway resistance
- Pharyngeal airway extends from posterior aspect of the nose to cricoid cartilage
- Glottic opening (triangular space formed between the true vocal cords) is the narrowest segment of the laryngeal opening in adults
- The glottic opening is used as the space through which one visualizes proper placement of the ETT
- The trachea begins at the level of the thyroid cartilage, C6, and bifurcates into the right and left main bronchi at T4-T5 (approximately the sternal angle)

### Methods of Supporting Airways

1. Non-definitive airway (patent airway)
   - Jaw thrust/chin lift
   - Oropharyngeal and nasopharyngeal airway
   - Bag mask ventilation
   - Laryngeal mask airway
2. Definitive airway (patent and protected airway)
   - Endotracheal tube
   - Surgical airway (cricothyrotomy or tracheostomy)

#### Tracheal Intubation

**Preparing for Intubation**

- Failed attempts at intubation can make further attempts more difficult due to tissue trauma
- Plan, prepare, and assess for potential difficulties (see Pre-Operative Assessment, A2)
- Ensure equipment is available and working (test ETT cuff, check laryngoscope light, machine check)
- Pre-oxygenate/denitrogenate: patient breathes 100% O2 for 3-5 min or for 4 vital capacity breaths
- May need to suction mouth and pharynx first

**Proper Positioning for Intubation**

- Align the three axes (mouth, pharynx, and larynx) to allow visualization from oral cavity to glottis
  - “Sniffing position”: flexion of lower C-spine (C5-C6), bow head forward, and extension of upper C-spine at atlanto-occipital joint (C1), nose in the air
- Contraindicated in known/suspected C-spine fracture/instability
- Proper position for laryngoscope tip to visualize cords is in epiglottic vallecula
Tube Insertion
• ETT insertion can incite a significant sympathetic response due to a "foreign body reflex" in the trachea, including tachycardia, dysrhythmias, myocardial ischemia, increased BP, and coughing
• a malpositioned ETT is a potential hazard for the intubated patient
  ▪ if too deep, may result in right endobronchial intubation, which is associated with left-sided atelectasis and right-sided tension pneumothorax
  ▪ if too shallow, may lead to accidental extubation, vocal cord trauma, or laryngeal paralysis as a result of pressure injury by the ETT cuff
• the tip of ETT should be located at the midpoint of the trachea at least 2 cm above the carina and the proximal end of the cuff should be placed at least 2 cm below the vocal cords
  ▪ approximately 20-23 cm mark at the right corner of the mouth for men and 19-21 cm for women

Confirmation of Tracheal Placement of ETT
• direct
  ▪ visualization of ETT passing through cords
  ▪ bronchoscopic visualization of ETT in trachea
• indirect
  ▪ EtCO2 in exhaled gas measured by capnography
  ▪ auscultate for equal breath sounds bilaterally and absent breath sounds over epigastrium
  ▪ bilateral chest movement, condensation of water vapor in ETT visible during exhalation and no abdominal distention
  ▪ refilling of reservoir bag during exhalation
  ▪ CXR (rarely done): ETT tip at midpoint of thoracic inlet and carina (lateral CXR more sensitive and specific)
• esophageal intubation suspected when
  ▪ EtCO2 zero or near zero on capnograph
  ▪ abnormal sounds during assisted ventilation
  ▪ impairment of chest excursion
  ▪ hypoxia/cyanosis
  ▪ presence of gastric contents in ETT
  ▪ distention of stomach/epigastrium with ventilation
Complications During Laryngoscopy and Intubation
- dental damage
- laceration (lips, gums, tongue, pharynx, esophagus)
- laryngeal trauma
- esophageal or endobronchial intubation
- accidental extubation
- insufficient cuff inflation or cuff laceration: results in leaking and aspiration
- laryngospasm (see Extubation, A18 for definition)
- bronchospasm

Difficult Airway
- difficulties with bag-mask ventilation, supraglottic airway, endotracheal intubation, infraglottic airway or surgical airway
- pre-operative assessment (history of previous difficult airway, airway examination) and pre-oxygenation are important preventative measures
- if difficult airway expected, consider
  - awake intubation
  - intubating with bronchoscope, trachlight (lighted stylet), fiber optic laryngoscope, glidescope, etc.
- if intubation unsuccessful after induction
  1. CALL FOR HELP
  2. ventilate with 100% O₂ via bag and mask
  3. consider returning to spontaneous ventilation and/or waking patient
- if bag and mask ventilation inadequate
  1. CALL FOR HELP
  2. attempt ventilation with oral airway
  3. consider/attempt LMA
  4. emergency invasive airway access (e.g. rigid bronchoscope, cricothyrotomy, or tracheostomy)

Oxygen Therapy
- in general, the goal of oxygen therapy is to maintain arterial oxygen saturation (SaO₂) >90%
- small decrease in saturation below SaO₂ of 90% corresponds to a large drop in arterial partial pressure of oxygen (PaO₂)
- in intubated patients, oxygen is delivered via the ETT
- in patients not intubated, there are many oxygen delivery systems available; the choice depends on oxygen requirements (FiO₂) and the degree to which precise control of delivery is needed
  - cyanosis can be detected at SaO₂ <85%, frank cyanosis at SaO₂ = 67%

Low Flow Systems
- acceptable if tidal volume 300-700 mL, respiratory rate (RR) <25, consistent ventilation pattern
- provide O₂ at flows between 0-10 L/min
- dilution of oxygen with room air results in a decrease in FiO₂
- an increase in minute ventilation (tidal volume x RR) results in a decrease in FiO₂
  - e.g. nasal canula (prong)
  - well tolerated if flow rates <5-6 L/min; drying of nasal mucosa at higher flows
  - nasopharynx acts as an anatomic reservoir that collects O₂
  - delivered oxygen concentration (FiO₂) can be estimated by adding 4% for every additional liter of O₂ delivered
  - provides FiO₂ of 24-44% at O₂ flow rates of 1-6 L/min

Reservoir Systems
- use a volume reservoir to accumulate oxygen during exhalation thus increasing the amount of oxygen available for the next breath
- simple face mask
  - covers patient’s nose and mouth and provides an additional reservoir beyond nasopharynx
  - fed by small bore O₂ tubing at a rate of at least 6 L/min to ensure that exhaled CO₂ is flushed through the exhalation ports and not rebreathed
  - provides FiO₂ of 55% at O₂ flow rates of 10 L/min
- non-rebreather mask
  - a reservoir bag and a series of one-way valves prevent expired gases from re-entering the bag during the exhalation phase, the bag accumulates with oxygen
  - provides FiO₂ of 80% at O₂ flow rates of 10-15 L/min
Venturi mask  • 
• delivers specific FiO₂ by varying the size of air entrainment 
• oxygen concentration determined by mask's port and NOT the wall flow rate 
• enables control of gas humidity 
• FiO₂ ranges from 24-50%

Modes of Ventilation
• hypercapnic respiratory failure: ventilator augments alveolar ventilation; may decrease the work of breathing, allowing respiratory muscles to rest 
• hypoxemic respiratory failure: ventilator provides supplemental oxygen, recruits atelectatic lung segments, helps improve V/Q mismatch, and decreases intrapulmonary shunt resistance) and underlying reason for mechanical ventilation 
• complications of mechanical ventilation 
  • airway complications 
    • tracheal stenosis, laryngeal edema 
    • alveolar complications 
    • ventilator-induced lung injury, ventilator-associated pneumonia (nosocomial pneumonia), barotrauma, volutrauma, inflammation, auto-PEEP, patient-ventilator asynchrony 
  • cardiovascular complications 
    • reduced venous return (secondary to increased intrathoracic pressure), reduced cardiac output, hypotension 
  • neuromuscular complications 
    • muscle atrophy 
    • increased intracranial pressure 
  • metabolic 
    • decreased CO₂ due to hyperventilation 
    • alkalemia with over correction of chronic hypercarbia

Ventilator Strategies
• mode and settings are determined based on patient factors (e.g. ideal body weight, compliance, resistance) and underlying reason for mechanical ventilation 
• hypoxemic respiratory failure: ventilator provides supplemental oxygen, recruits atelectatic lung segments, helps improve V/Q mismatch, and decreases intrapulmonary shunt 
• hypercapnic respiratory failure: ventilator augments alveolar ventilation; may decrease the work of breathing, allowing respiratory muscles to rest 

High Flow Systems
• generate flows of up to 50-60 L/min 
• meet/exceed patient's inspiratory flow requirement 
• deliver consistent and predictable concentration of O₂ 
• Venturi mask
  • mode and settings are determined based on patient factors (e.g. ideal body weight, compliance, resistance) and underlying reason for mechanical ventilation 
• hypercapnic respiratory failure: ventilator augments alveolar ventilation; may decrease the work of breathing, allowing respiratory muscles to rest 
• hypoxemic respiratory failure: ventilator provides supplemental oxygen, recruits atelectatic lung segments, helps improve V/Q mismatch, and decreases intrapulmonary shunt resistance) and underlying reason for mechanical ventilation 
• complications of mechanical ventilation 
  • airway complications 
    • tracheal stenosis, laryngeal edema 
    • alveolar complications 
    • ventilator-induced lung injury, ventilator-associated pneumonia (nosocomial pneumonia), barotrauma, volutrauma, inflammation, auto-PEEP, patient-ventilator asynchrony 
  • cardiovascular complications 
    • reduced venous return (secondary to increased intrathoracic pressure), reduced cardiac output, hypotension 
  • neuromuscular complications 
    • muscle atrophy 
    • increased intracranial pressure 
  • metabolic 
    • decreased CO₂ due to hyperventilation 
    • alkalemia with over correction of chronic hypercarbia

Ventilation
• ventilation is maintained with PPV in patients given muscle relaxants 
• assisted or controlled ventilation can also be used to assist spontaneous respirations in patients not given muscle relaxants as an artificial means of supporting ventilation and oxygenation 

Mechanical Ventilation
• indications for mechanical ventilation 
  • apnea 
  • hypventilation/acute respiratory acidosis 
  • intraoperative positioning limiting respiratory excursion (e.g. prone, Trendelenburg) 
  • required hyperventilation (to lower ICP) 
  • deliver positive end expiratory pressure (PEEP) 
  • increased intrathoracic pressure (e.g. laparoscopic procedure) 
• complications of mechanical ventilation 
  • airway complications 
    • tracheal stenosis, laryngeal edema 
    • alveolar complications 
    • ventilator-induced lung injury, ventilator-associated pneumonia (nosocomial pneumonia), barotrauma, volutrauma, inflammation, auto-PEEP, patient-ventilator asynchrony 
  • cardiovascular complications 
    • reduced venous return (secondary to increased intrathoracic pressure), reduced cardiac output, hypotension 
  • neuromuscular complications 
    • muscle atrophy 
    • increased intracranial pressure 
  • metabolic 
    • decreased CO₂ due to hyperventilation 
    • alkalemia with over correction of chronic hypercarbia

Modes of Ventilation
• assist-control ventilation (ACV) 
  • every breath is delivered with a pre-set tidal volume and rate or minute ventilation 
  • extra controlled breaths may be triggered by patient effort; if no effort is detected within a specified amount of time the ventilator will initiate the breath 
• pressure control ventilation (PCV) 
  • a minimum frequency is set and patient may trigger additional breaths above the ventilator 
  • all breaths delivered at a preset constant inspiratory pressure 
• synchronous intermittent mandatory ventilation (SIMV) 
  • ventilator provides controlled breaths (either at a set volume or pressure) 
  • patient can breathe spontaneously (these breaths may be pressure supported) between controlled breaths 
• pressure support ventilation (PSV) 
  • patient initiates all breaths and the ventilator supports each breath with a pre-set inspiratory pressure 
  • useful for weaning off ventilator 
• high-frequency oscillatory ventilation (HFOV) 
  • high breathing rate (up to 900 breaths/min in an adult), very low tidal volumes 
  • used commonly in neonatal and pediatric respiratory failure 
  • used in adults when conventional mechanical ventilation is failing
non-invasive positive pressure ventilation (NPPV)
- achieved without intubation by using a nasal or face mask with
  - BiPAP: increased pressure (like PSV) on inspiration and lower constant pressure on expiration
  - CPAP: delivers constant pressure on both inspiration and expiration

Intraoperative Monitoring

Temperature

Causes of Hypothermia (<36.0°C)
- intraoperative temperature losses are common (e.g. 90% of intraoperative heat loss is transcutaneous), due to:
  - OR environment (cold room, IV fluids, instruments)
  - open wound
  - prevent with inflated warming blanket and warmed IV fluids

Causes of Hyperthermia (>37.5-38.3°C)
- drugs (e.g. atropine)
- blood transfusion reaction
- infection/sepsis
- medical disorder (e.g. thyrotoxicosis)
- malignant hyperthermia (see Uncommon Complications, A26)
- over-zealous warming efforts

Heart Rate

Intraoperative Tachycardia
- tachycardia = HR >150 bpm; divided into narrow complex supraventricular tachycardias (SVT) or wide complex tachycardias
- SVT: sinus tachycardia, atrial fibrillation/flutter, accessory pathway mediated tachycardia, paroxysmal atrial tachycardia
- wide complex tachycardia: VT, SVT with aberrant conduction
- causes of sinus tachycardia:
  - shock/hypovolemia/blood loss
  - anxiety/pain/light anesthesia
  - full bladder
  - anemia
  - febrile illness/sepsis
  - drugs (e.g. atropine, cocaine, dopamine, epinephrine, ephedrine, isoflurane, isoproterenol, pancuronium)
  - Addisonian crisis, hypoglycemia, transfusion reaction, malignant hyperthermia
- for management of tachycardia, see ACLS Guidelines (Figure 16), A32
Intraoperative Bradycardia
• bradycardia = HR <50 bpm; most concerning are 2nd degree (Type 2 Mobitz) and 3rd degree heart block, which can both degenerate into asystole
• causes of sinus bradycardia
  ▪ increased parasympathetic tone vs. decreased sympathetic tone
  ▪ must rule out hypoxemia
  ▪ arrhythmias (see Cardiology and Cardiac Surgery, C15)
  ▪ baroreceptor reflex due to increased ICP or increased BP
  ▪ vagal reflex (oculocardiac reflex, carotid sinus reflex, airway manipulation)
  ▪ drugs (e.g. Sch, opioids, edrophonium, neostigmine, halothane, digoxin, β-blockers)
  ▪ high spinal/epidural anesthesia
• for management of bradycardia, see ACLS Guidelines (Figure 16), A32

Cardiac Arrest
• pulseless arrest occurs due to 4 cardiac rhythms divided into shockable and non-shockable rhythms
  ▪ shockable: ventricular fibrillation (VF) and ventricular tachycardia (VT)
  ▪ non-shockable: asystole and pulseless electrical activity (PEA)
• for VF/VT, key to survival is good early CPR and defibrillation
• for asystole/PEA, key to survival is good early CPR and exclude all reversible causes
• reversible causes of PEA arrest (5 Hs and 5 Ts)
  ▪ 5 Hs: hypothermia, hypovolemia, hypoxia, hydrogen ions (acidosis), hypo/hyperkalemia
  ▪ 5 Ts: tamponade (cardiac), thrombosis (pulmonary), thrombosis (coronary), tension pneumothorax, toxins (overdose/poisoning)
• for management of cardiac arrest, see ACLS Guidelines (Figure 16), A32

Note
- Goal is to maintain urine output at >0.5 mL/kg/h

Causes of Intraoperative Hypotension/Shock
• shock: condition characterized by inability of cardiovascular system to maintain adequate end-organ perfusion
  a) hypovolemic/hemorrhagic shock
    • most common form of shock, due to decrease in intravascular volume
  b) obstructive shock
    • obstruction of blood into or out of the heart
    • increased JVP, distended neck veins, increased systemic vascular resistance, insufficient cardiac output (CO)
    • e.g. tension pneumothorax, cardiac tamponade, pulmonary embolism
  c) cardiogenic shock
    • myocardial dysfunction
    • increased JVP, distended neck veins, increased systemic vascular resistance, decreased CO
    • e.g. dysrhythmias, ischemia/infarct, cardiomyopathy, acute valvular dysfunction
  d) septic shock
    • see Infectious Diseases, ID22
    • bacterial, viral, fungal, endotoxins/mediators cause vasodilation and capillary leakage
    • associated with contamination of open wounds, intestinal injury or penetrating trauma
    • signs: fever, decreased JVP, wide pulse pressure, increased CO, increased HR, decreased systemic vascular resistance ± pressors
    • initial treatment: antibiotics, volume expansion
  e) spinal/neurogenic shock
    • decreased sympathetic tone
    • hypotension without tachycardia or peripheral vasoconstriction (warm skin)
f) anaphylactic shock
  - acute/subacute generalized allergic reaction due to an inappropriate or excessive immune response (type 1 hypersensitivity)
  - treatment of anaphylactic shock
    - moderate reaction: generalized urticaria, angioedema, wheezing, tachycardia
      - epinephrine (1:1000) 0.3-0.5 mg SC
      - antihistamines: diphenhydramine (Benadryl®) 25-50 mg IM
      - salbutamol (Ventolin®) 1 cc via MDI
    - severe reaction/evolution: severe wheezing, laryngeal/pulmonary edema, shock
      - ABCs, may need ETT due to airway edema
      - epinephrine (1:1000) 0.1-0.3 mg IV (or via ETT if no IV access) to start, repeat as needed
      - antihistamines: diphenhydramine (Benadryl®) 50 mg IV (~1 mg/kg)
      - steroids: hydrocortisone 100 mg IV (~1.5 mg/kg) or methylprednisolone (Solumedrol®) 1 mg/kg IV q6h x 24 h
      - large volumes of crystalloid may be required

g) drugs
  - vasodilators, high spinal anesthetic interfering with sympathetic outflow

h) other
  - transfusion reaction, Addisonian crisis, thyrotoxicosis, hypothyroid, aortocaval syndrome
  - see Hematology, H54 and Endocrinology, E35, E22, E26

Causes of Intraoperative HTN
- inadequate anesthesia causing pain and anxiety
- pre-existing HTN, coarctation or preeclampsia
- hypoxemia/hypercarbia
- hypervolemia
- drugs (e.g. ephedrine, epinephrine, cocaine, phenylephrine, ketamine)
- allergic/anaphylactic reaction
- hypermetabolic states: malignant hyperthermia, neuroleptic malignant syndrome, thyroid storm, pheochromocytoma (see Endocrinology, E25, E36)

Fluid Balance and Resuscitation
- total requirement = maintenance + deficit + ongoing loss
- in surgical settings this formula must take into account multiple factors including pre-operative fasting/decreased fluid intake, increased losses during or before surgery, fluid shifting during surgery, fluids given with blood products and medications

What is the Maintenance?
- average healthy adult requires approximately 2500 mL water/d
  - 200 mL/d GI losses
  - 800 mL/d insensible losses (respiration, perspiration)
  - 1500 mL/d urine (be aware of renal failure)
- 4:2:1 rule to calculate maintenance requirements (applies to crystalloids only)
  - 4 mL/kg/h first 10 kg
  - 2 mL/kg/h second 10 kg
  - 1 mL/kg/h for remaining weight >20 kg
- increased requirements with fever, sweating, GI losses (vomiting, diarrhea, NG suction), adrenal insufficiency, hyperventilation, and polyuric renal disease
- decreased requirements with anuria/oliguria, SIADH, highly humidified atmospheres, and CHF
- maintenance electrolytes
  - Na+: 3 mEq/kg/d
  - K+: 1 mEq/kg/d
- 50 kg patient maintenance requirements
  - fluid = 40 + 20 + 30 = 90 mL/h = 2160 mL/d = 2.16 L/d
  - Na+ = 150 mEq/d (therefore 150 mEq / 2.16 L/d = 69 mEq/L)
  - K+ = 50 mEq/d (therefore 50 mEq / 2.16 L/d = 23 mEq/L)
- above patient's requirements roughly met with 2/3 D5W, 1/3 NS
- 2/3 + 1/3 at 100 mL/h with 20 mEq KCl per liter

What is the Deficit?
- patients should be adequately hydrated prior to anesthesia
- total body water (TBW) = 60% or 50% of total body weight for an adult male or female, respectively (e.g. for a 70 kg adult male TBW = 70 x 0.6 = 42 L)
- total Na+ content determines ECF volume; [Na+] determines ICF volume
• hypovolemia due to volume contraction
  ▪ extra-renal Na⁺ loss
    - GI: vomiting, NG suction, drainage, fistulae, diarrhea
    - skin/respiratory: insensible losses (fever), sweating, burns
  ▪ vascular: hemorrhage
  ▪ renal Na⁺ and H₂O loss
  ▪ diuretics
  ▪ osmotic diuresis
  ▪ hypoaldosteronism
  ▪ salt-wasting nephropathies
  ▪ renal H₂O loss
  ▪ diabetes insipidus (central or nephrogenic)
  ▪ hypovolemia with normal or expanded ECF volume
    - decreased CO
    - redistribution
      - hypoalbuminemia: cirrhosis, nephrotic syndrome
      - capillary leakage: acute pancreatitis, rhabdomyolysis, ischemic bowel, sepsis, anaphylaxis
• replace water and electrolytes as determined by patient’s needs
• with chronic hyponatremia, correction must be done gradually over >48 h to avoid central pontine myelinolysis

What are the Ongoing Losses?
• tubes
  ▪ Foley catheter, NG, surgical drains
• third-spacing (other than ECF, ICF)
  ▪ pleura, GI, retroperitoneal, peritoneal
  ▪ evaporation via exposed viscera, burns
• blood loss
• ongoing loss due to surgical exposure and evaporative losses

IV Fluids
• replacement fluids include crystalloid and colloid solutions
• IV fluids improve perfusion but NOT O₂ carrying capacity of blood

Initial Distribution of IV Fluids
• H₂O follows ions/molecules to their respective compartments

Crystalloid Infusion
• salt-containing solutions that distribute within ECF
• maintain euvoolemia in patient with blood loss: 3 mL crystalloid infusion per 1 mL of blood loss for volume replacement (i.e. 3:1 replacement)
• if large volumes are to be given, use balanced fluids such as Ringer’s lactate or Plasmalyte®, as too much normal saline (NS) may lead to hyperchloremic metabolic acidosis

Colloid Infusion
• includes protein colloids (albumin and gelatin solutions) and non-protein colloids (dextrans and starches e.g. hydroxyethyl starch [HES])
• distributes within intravascular volume
• 1:1 ratio (infusion:blood loss) only in terms of replacing intravascular volume
• HES colloids remain in intravascular space (metabolized by plasma serum amylase and renally excreted)
• the use of HES solutions is controversial because of recent RCTs and meta-analyses highlighting their renal and coagulopathic side effects, as well as a lack of specific indications for their use
• colloids are being used based on mechanistic and experimental evidence but there is a paucity of definitive studies investigating their safety and efficacy; routine use of colloids should be avoided

Colloids vs. Crystalloids for Fluid Resuscitation in Critically Ill Patients
Cochrane DB Syst Rev 2012;6:CD000567
Purpose: To evaluate the effects of colloids compared to crystalloids for fluid resuscitation, specifically when used in critically ill patients.
Methods: A meta-analysis was performed looking at randomized controlled trials comparing colloids vs. crystalloid use in patients requiring volume replacement. Pregnant women and neonates were excluded. Primary outcome was overall mortality.
Results: Results were broken down based on specific colloid. For albumin (or plasma protein fraction) the relative risk (RR) was 1.01 (95% CI 0.93-1.10) as compared to crystalloid. For hydroxyethyl starch the RR was 1.10 (95% CI 0.91-1.32). Modified gelatin had a RR of 0.91 (95% CI 0.49-1.72) and Dextran had a RR of 1.24 (95% CI 0.94-1.65). For colloids mixed in a hypertonic crystalloid as compared to isotonic crystalloid the RR was 0.88 (95% CI 0.71-1.06).
Conclusions: There is no evidence that use of colloids improves survival in trauma patients, burn patients, or post-operative patients when compared to crystalloid solutions. Given the increased cost of colloids as compared to crystalloids, it is recommended that crystalloids be the fluid of choice in these patients.
### Blood Products

- see Hematology, H52

#### Red Blood Cells (RBCs)
- 1U RBCs (approx. 300 ml) increases Hb by 10 g/L in a 70 kg patient
- RBCs may be diluted with colloid/crystalloid to decrease viscosity
- decision to transfuse based on initial blood volume, premorbid Hb level, present volume status, expected further blood loss, patient health status, patient consent
- massive transfusion ≥1 x blood volume/24 h

#### Autologous RBCs
- replacement of blood volume with one’s own RBCs
- may decrease complications (infectious, febrile, etc.)
- alternative to homologous transfusion in elective procedures, but only if adequate Hb and no infection
- pre-operative phlebotomy prior to elective surgery (up to 3U collected 3-5 wk before surgery)
- intraoperative salvage and filtration (cell saver); contraindicated in contaminated (e.g. bowel, abscess) or cancer cases

#### Non-RBC Products
- fresh frozen plasma (FFP)
  - contains all plasma clotting factors and fibrinogen close to normal plasma levels
  - to prevent/treat bleeding due to coagulation factor depletion/deficiencies, liver impairment
- cryoprecipitate
  - contains Factors VIII and XIII, von Willebrand Factor (vWF), fibrinogen
- platelets
  - used in thrombocytopenia, massive transfusions, impaired platelet function
- albumin
  - selective intravascular volume expander
- erythropoietin
  - can be used pre-operatively to stimulate erythropoiesis

#### Complications Due to Transfusion
- infectious risks: HIV, hepatitis B/C, Epstein-Barr virus (EBV), cytomegalovirus (CMV), brucellosis, malaria, salmonellosis, measles, syphilis
- hypervolemia
- electrolyte changes: increased K+ in stored blood
- dilutional coagulopathy
- dilutional thrombocytopenia
- hypothermia
- citrate toxicity
- hypocalcemia
- iron overload
- transfusion-related immunosuppression: perioperative transfusion may be associated with increased risk of post-operative infection, increased short-term mortality and possible cancer recurrence
- see Hematology, H54 for list of transfusion reactions

### Calculating Acceptable Blood Losses (ABL)

- Blood volume
  - term infant 80 mL/kg
  - adult male 70 mL/kg
  - adult female 60 mL/kg

- Calculate estimated blood volume (EBV) (e.g. in a 70 kg male, approx. 70 mL/kg)
  - EBV = 70 kg x 70 mL/kg = 4900 mL

- Decide on a transfusion trigger, i.e. the Hb level at which you would begin transfusion, (e.g. 70 g/L for a person with Hb₁(0) = 150 g/L)
  - Hb(0) = 70 g/L

- Calculate ABL = Hct₁(0) – Hct(H) x EBV
  - Hct₁(0) = 150 – 70 x 4900
  - = 2613 mL

- Therefore in order to keep the Hb level above 70 g/L, RBCs would have to be given after approximately 2.6 L of blood has been lost

### A Multicentre, Randomized, Controlled Clinical Trial of Transfusion Requirements in Critical Care

**Purpose**: To determine whether a restrictive strategy of RBC transfusion and a liberal strategy produce equivalent results in critically ill patients.

**Study**: Randomized controlled trial with 85-d follow-up.

**Patients**: 1,329 critically ill patients with sepsis after initial treatment who had Hb concentrations of <90 g/L within 72 h after admission to the ICU.

**Mean age**: 57.5 yr; 62.5% male.

**Intervention**: Patients were randomly assigned to either a restrictive strategy of transfusion, in which RBCs were transfused if the Hb dropped <70 g/L, or a liberal strategy, in which transfusions were given when the Hb dropped <100 g/L and Hb concentrations were maintained between 70-90 g/L.

**Main Outcomes**: All cause mortality rates at 30 d and 60 d, mortality rates during the stay in ICU and hospitalization, survival times during the first 30 d, and rates of organ failure and dysfunction.

**Results**: Overall, 30 d mortality was similar in the two groups. However, the rates were significantly lower with the restrictive strategy of RBC transfusion and a liberal strategy produce equivalent results in critically ill patients.

**Conclusions**: With the possible exception of patients with acute MI and unstable angina, a restrictive strategy of RBC transfusion is as effective as, and possibly superior to, a liberal transfusion strategy in critically ill patients.
**Types of Anesthesia**

- **general**
  - general anesthesia (GA)
  - total IV anesthesia (TIVA)

- **regional**
  - spinal, epidural
  - peripheral nerve block
  - IV regional

- **local**
  - local infiltration
  - topical

- **sedation**
  - monitored anesthesia care
  - note that different types of anesthesia can be combined (general + regional)

**General Anesthesia**
- induction, maintenance and extubation

---

**Induction**

**Routine Induction vs. Rapid Sequence Induction**

- routine induction is the standard in general anesthesia, however a RSI is indicated in patients at risk of regurgitation/aspiration (see Aspiration, A5)
- RSI uses pre-determined doses of induction drugs given at set times

**Table 8. Comparison of Routine Induction vs. RSI**

<table>
<thead>
<tr>
<th>Steps</th>
<th>Routine Induction</th>
<th>RSI</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Equipment Preparation</td>
<td>Check equipment, drugs, suction, and monitors; prepare an alternative laryngoscope blade and a second ETT tube one size smaller</td>
<td>Use agent of choice to blunt physiologic responses to airway manipulation 3 min prior to laryngoscopy</td>
</tr>
<tr>
<td>2. Pre-Oxygenation/Denitrogenation</td>
<td>100% O₂ for 3 min or 4 vital capacity breaths</td>
<td>Use agent of choice to blunt physiologic responses to airway manipulation; if possible, give 3 min prior to laryngoscopy, but can skip this step in an emergent situation</td>
</tr>
<tr>
<td>3. Pre-Treatment Agents</td>
<td>Use agent of choice to blunt physiologic responses to airway manipulation 3 min prior to laryngoscopy</td>
<td>Use agent of choice to blunt physiologic responses to airway manipulation; if possible, give 3 min prior to laryngoscopy, but can skip this step in an emergent situation</td>
</tr>
<tr>
<td>4. Induction Agents</td>
<td>Use IV or inhalation induction agent of choice</td>
<td>Use pre-determined dose of fast acting induction agent of choice</td>
</tr>
<tr>
<td>5. Muscle Relaxants</td>
<td>Muscle relaxant of choice given after the onset of the induction agent</td>
<td>Pre-determined dose of fast acting muscle relaxant (e.g. SCh) given IMMEDIATELY after induction agent</td>
</tr>
<tr>
<td>6. Ventilation</td>
<td>Bag-mask ventilation</td>
<td>DO NOT bag ventilate – can increase risk of aspiration</td>
</tr>
<tr>
<td>7. Cricoid Pressure</td>
<td>Backwards upwards rightwards pressure (BURP) to assist visualization if indicated</td>
<td>Sellick maneuver, also known as cricoid pressure, to prevent regurgitation and assist in visualization (2 kg pressure with drowsiness, 3 kg with loss of consciousness)</td>
</tr>
<tr>
<td>8. Intubation</td>
<td>Intubate, inflate cuff, confirm ETT position</td>
<td>Intubate once paralyzed (~45 s after SCh given), inflate cuff, confirm ETT position, cricoid pressure maintained until ETT cuff inflated and placement confirmed</td>
</tr>
</tbody>
</table>

**Induction Agents**

- induction in general anesthesia may be achieved with intravenous agents, volatile inhalation agents, or both

**Intravenous Agents**

- see Table 11, A27
- IV induction agents are non-opioid drugs used to provide amnesia and blunt reflexes
- these are initially used to draw the patient into the maintenance phase of general anesthesia rapidly, smoothly and with little adverse effects
  - examples include propofol, sodium thiopental (not available in North America), or ketamine
  - a continuous propofol infusion may also be used for the maintenance phase of GA

---

**Solubility of Volatile Anesthetics in Blood**

- Least Soluble to Most Soluble
  - Nitrous oxide < desflurane < sevoflurane < isoflurane < halothane
Volatile Inhalational Agents
- examples include sevoflurane, desflurane, isoflurane, enflurane, halothane, and nitrous oxide
- see Table 14, A28

MAC (Minimum Alveolar Concentration)
- the alveolar concentration of a volatile anesthetic at one atmosphere (atm) of pressure that will prevent movement in 50% of patients in response to a surgical stimulus (e.g. abdominal incision)
- 1.2-1.3 times MAC will often ablate response to stimuli in the general population
- potency of inhalational agents is compared using MAC
- MAC values are roughly additive when mixing N₂O with another volatile agent; however, this only applies to movement, not other effects such as BP changes (e.g. 0.5 MAC of a potent agent + 0.5 MAC of N₂O = 1 MAC of potent agent)
- MAC-intubation: the MAC of anesthetic that will inhibit movement and coughing during endotracheal intubation, generally 1.3 MAC
- MAC-block adrenergic response (MAC-BAR): the MAC necessary to blunt the sympathetic response to noxious stimuli, generally 1.5 MAC
- MAC-awake: the MAC of a given volatile anesthetic at which a patient will open their eyes to command, usually 0.3-0.4 of the usual MAC value

Muscle Relaxants and Reversing Agents

Muscle Relaxants
- two types of muscle relaxants
  1. depolarizing muscle relaxants: succinylcholine (SCh)
  2. non-depolarizing muscle relaxants: rocuronium, mivacurium, vecuronium, cistracurium, pancuronium
- see Tables 15 and 16, A29 for more details including mechanism of action
- block nicotinic cholinergic receptors in NMJ
- provides skeletal muscle paralysis, including the diaphragm, but spares involuntary muscles such as the heart and smooth muscle
- never use muscle relaxants without adequate preparation and equipment to maintain airway and ventilation
- muscle relaxation produces the following desired effects
  1. facilitates intubation
  2. assists with mechanical ventilation
  3. prevents muscle stretch reflex and decreases muscle tone
  4. allows access to the surgical field (intracavitary surgery)
  5. nerve stimulator (i.e. train of four) is used intraoperatively to assess the degree of nerve block; no twitch response seen with complete neuromuscular blockade

Determinants of Speed of Onset of Volatile Anesthetics
- Solubility: decrease solubility → increase rate of induction
- Cardiac output (CO): as CO increases, anesthetic uptake to blood increases and alveolar gas concentration decreases, thus delaying induction
- Partial pressure difference between alveolar and venous blood: increase gradient → decrease rate of induction
- Inspired gas concentration: increase inspired concentration → increase rate of induction
- Alveolar ventilation: increase alveolar ventilation → increase rate of induction
- Second gas effect: when 2 gases are administered together, uptake of the first gas (e.g. N₂O) increases the alveolar concentration of the second gas (e.g. desflurane), increasing rate of induction
Reversing Agents
- neostigmine, pyridostigmine, edrophonium (see Table 17, A30)
- reversal agents are acetylcholinesterase inhibitors
  - inhibits enzymatic degradation of ACh; increases amount of ACh at nicotinic and muscarinic receptors, displacing non-depolarizing muscle relaxant
  - administer reversal agents when there has been some recovery of blockade (i.e. muscle twitch)
  - can only reverse the effect of non-depolarizing muscle relaxants
- anticholinergic agents (e.g. atropine, glycopyrrolate) are simultaneously administered to minimize muscarinic effect of reversal agents (i.e. bradycardia, salivation and increased bowel peristalsis)

Analgesia
- options include opioids (e.g. morphine, fentanyl, hydromorphone), NSAIDS, acetaminophen, local, and regional anesthetic (see Table 12, A28)

Maintenance
- general anesthesia is maintained using volatile inhalation agents and/or IV agents (i.e. propofol infusion)
- analgesia (usually IV opioids) and muscle relaxants are also given as needed

Extubation
- criteria
  - patient must no longer have intubation requirements (see Table 2, A7)
  - patency: airway must be patent
  - protection: airway reflexes intact
  - patient must be oxygenating and ventilating spontaneously
- general guidelines
  - ensure patient has normal neuromuscular function (peripheral nerve stimulator monitoring) and hemodynamic status
  - ensure patient is breathing spontaneously with adequate rate and tidal volume
  - allow ventilation (spontaneous or controlled) with 100% O₂ for 3-5 min
  - suction secretions from pharynx
  - deflate cuff, remove ETT on inspiration (vocal cords abducted)
  - ensure patient is breathing adequately after extubation
  - ensure face mask for O₂ delivery available
  - proper positioning of patient during transfer to recovery room (supine, head elevated)

Complications of Extubation
- early extubation
  - aspiration
  - laryngospasm
- late extubation
  - transient vocal cord incompetence
  - edema (glottic, subglottic)
  - pharyngitis, tracheitis

Laryngospasm
- defined as forceful involuntary spasm of laryngeal muscles caused by stimulation of superior laryngeal nerve (by oropharyngeal secretions, blood, extubation)
- causes partial or total airway obstruction
- more likely to occur in semi-conscious patients
- prevention: extubate while patient is still deeply under anesthesia or fully awake
- treatment: bag-mask ventilation with 100% oxygen, low-dose propofol (0.5-1.0 mg/kg) optional, low-dose succinylcholine (0.25-1 mg/kg) and reintubation if hypoxia develops
Regional Anesthesia

- local anesthetic agent (LA) applied around a peripheral nerve at any point along the length of the nerve (from spinal cord up to, but not including, the nerve endings) for the purpose of reducing or preventing impulse transmission
- no CNS depression (unless overdose of local anesthetic); patient remains conscious
- regional anesthetic techniques categorized as follows:
  - epidural and spinal anesthesia (neuraxial anesthesia)
  - peripheral nerve blocks
  - IV regional anesthesia (e.g. Bier block)

Patient Preparation
- sedation may be indicated before block
- monitoring should be as extensive as for general anesthesia

Relative Indications for Regional Anesthesia
- patient preference
- superior postoperative analgesia
- decreased incidence of PONV
- shorter recovery and improved rehabilitation
- general anesthesia not available/contraindicated
- differential blockade (to block pain but preserve motor function)

Complications of Regional Anesthesia
- failure of technique/inadequate anesthesia
- unintentional total spinal anesthesia
- systemic drug toxicity due to overdose or intravascular injection (see Local Anesthesia, A21)
- injury to nerve root/spinal cord (nerve deficit), epidural vein (hematoma), peripheral nerve (intraneural injection)
- infection (e.g. osteitis, epidural abscess, meningitis)

Epidural and Spinal Anesthesia

- most useful for surgeries performed below level of umbilicus

Anatomy of Spinal/Epidural Area
- spinal cord extends to L2, dural sac to S2 in adults
- nerve roots (cauda equina) from L2 to S2
- needle inserted below L2 should not encounter cord, thus L3-L4, L4-L5 interspace commonly used
- structures penetrated
  - skin
  - subcutaneous fat
  - supraspinous ligament
  - interspinous ligament
  - ligamentum flavum (last layer before epidural space)
  - dura + arachnoid for spinal anesthesia

Table 9. Epidural vs. Spinal Anesthesia

<table>
<thead>
<tr>
<th></th>

</tr>
</tbody>
</table>

Benefits of Regional Anesthesia
- Reduced perioperative pulmonary complications
- Reduced perioperative analgesia requirements
- Decreased PONV
- Reduced perioperative blood loss
- Ability to monitor CNS status during procedure
- Improved perfusion
- Lower incidence of VTE

Epidural and Spinal Anesthesia

Anatomy of Spinal/Epidural Area

Spinous processes should be maximally flexed
L4 spinal processes found between iliac crests
Common sites of insertion are L3-L4 and L4-L5

Landmarking Epidural/Spinal Anesthesia

Spinous processes should be maximally flexed
L4 spinal processes found between iliac crests
Common sites of insertion are L3-L4 and L4-L5

Combined Spinal-Epidural

Combines the benefits of rapid, reliable, intense blockade of spinal anesthesia together with the flexibility of an epidural catheter

Contraindications to Spinal/Epidural Anesthesia

- absolute contraindications
  - lack of trained personnel
  - lack of resuscitative drugs/equipment
  - patient refusal
  - allergy to local anesthetic
  - infection at puncture site or underlying tissues
  - coagulopathies/bleeding diathesis
  - raised ICP
  - sepsis/bacteremia
  - severe hypovolemia
  - cardiac lesion with fixed output states (e.g. severe mitral/aortic stenosis)
  - lack of IV access
- relative contraindications
  - pre-existing neurological disease (demyelinating lesions)
  - previous spinal injection, severe spinal deformity
  - prolonged surgery
  - major blood loss or maneuvers that can compromise reaction

Peripheral Nerve Blocks

- deposition of LA around the target nerve or plexus
- ultrasound guidance and peripheral nerve stimulation (needle will stimulate target nerve/plexus) may be used to guide needle to target nerve while avoiding neural trauma or intraneural injection
- approximately 2-4 per 10,000 risk of late neurologic injury
- most major nerves or nerve plexi can be targeted (e.g. brachial plexus block, femoral nerve block, sciatic nerve block, etc.)
- performed with standard monitors
- resuscitation equipment must be available

Contraindications to Peripheral Nerve Blockade

- absolute contraindications
  - allergy to LA
  - patient refusal
- relative contraindications
  - certain types of pre-existing neurological dysfunction (e.g. ALS, MS, diabetic neuropathy)
  - local infection at block site
  - bleeding disorder

Classic Presentation of Dural Puncture Headache

- Onset 6 h-3 d after dural puncture
- Postural component (worse sitting)
- Occipital or frontal localization
- ± tinnitus, diplopia

Reduction of Post-Operative Mortality and Morbidity with Epidural or Spinal Anaesthesia: Results from Overview of Randomized Trials

BMJ 2000;321:1-12

Purpose: To obtain reliable estimates of the effects of neuraxial blockade with epidural or spinal anaesthesia on post-operative morbidity and mortality after various surgeries with or without general anesthesia.

Study: Systematic review of all trials with randomization to intraoperative neuraxial blockade vs. control group.

Patients: 141 trials including 9,559 patients.

Main Outcomes: All cause mortality, MI, PE, DVT, transfusion requirements, pneumonia, other infections, respiratory depression, and renal failure.

Results: With neuraxial blockade, overall mortality was reduced by about one third. Neuraxial blockade reduced the risk of PE by 55%, DVT by 44%, transfusion requirements by 50%, pneumonia by 39%, and respiratory depression by 59%. There were also reductions in MI and renal failure. These mortality reductions are irrespective of surgical group, type of blockade (epidural or spinal), or whether neuraxial blocker was combined with general anesthetic.

Conclusions: Neuraxial blockade reduces post-operative mortality, and other serious complications.
Local Anesthesia

Local Anesthetic Agents

- see Table 18, A30 for list of LA agents

Definition and Mode of Action
- LA are drugs that block the generation and propagation of impulses in excitable tissues: nerves, skeletal muscle, cardiac muscle, brain
- LA bind to receptors on the cytosolic side of the Na⁺ channel, inhibiting Na⁺ flux and thus blocking impulse conduction
- different types of nerve fibers undergo blockade at different rates

Absorption, Distribution, Metabolism
- LA readily crosses the blood-brain barrier (BBB) once absorbed into the bloodstream
- ester-type LA (procaine, tetracaine) are broken down by plasma and hepatic esterases; metabolites excreted via kidneys
- amide-type LA (lidocaine, bupivicaine) are broken down by hepatic mixed-function oxidases (P450 system); metabolites excreted via kidneys

Selection of LA
- choice of LA depends on
  - onset of action: influenced by pKa (the lower the pKa, the higher the concentration of the base form of the LA, and the faster the onset of action)
  - duration of desired effects: influenced by protein binding (longer duration of action when protein binding of LA is strong)
  - potency: influenced by lipid solubility (agents with high lipid solubility penetrate the nerve membrane more easily)
  - unique needs (e.g. sensory blockade with relative preservation of motor function by bupivicaine at low doses)
  - potential for toxicity

Systemic Toxicity
- see Table 18, A30 for maximum doses, potency, and duration of action for common LA agents
- occurs by accidental intravascular injection, LA overdose, or unexpectedly rapid absorption
- CNS effects
  - CNS effects first appear to be excitatory due to initial block of inhibitory fibers, then subsequent block of excitatory fibers
  - effects in order of appearance
    - numbness of tongue, perioral tingling, metallic taste
    - disorientation, drowsiness
    - tinnitus
    - visual disturbances
    - muscle twitching, tremors
    - unconsciousness
    - convulsions, seizures
    - generalized CNS depression, coma, respiratory arrest
- CVS effects
  - vasodilation, hypotension
  - decreased myocardial contractility
  - dose-dependent delay in cardiac impulse transmission
    - prolonged PR, QRS intervals
    - sinus bradycardia
  - CVS collapse
- treatment of systemic toxicity
  - early recognition of signs, get help
  - 100% O₂, manage ABCs
  - diazepam or sodium thiopental may be used to increase seizure threshold
  - manage arrhythmias (see ACLS Guidelines, A32)
  - Intralipid 20% to bind local anesthesic in circulation

Figure 10. Local anesthetic systemic toxicity
Local Infiltration and Hematoma Blocks

Local Infiltration
- injection of tissue with LA, producing a lack of sensation in the infiltrated area due to LA acting on nerves
- suitable for small incisions, suturing, excising small lesions
- can use fairly large volumes of dilute LA to infiltrate a large area
- low concentrations of epinephrine (1:100,000-1:200,000) cause vasoconstriction, thus reducing bleeding and prolonging the effects of LA by reducing systemic absorption

Fracture Hematoma Block
- special type of local infiltration for pain control during manipulation of certain fractures
- hematoma created by fracture is infiltrated with LA to anesthetize surrounding tissues
- sensory blockade may only be partial
- no muscle relaxation

Topical Anesthetics
- various preparations of local anesthetics available for topical use, may be a mixture of agents (EMLA cream is a combination of 2.5% lidocaine and prilocaine)
- must be able to penetrate the skin or mucous membrane

Post-Operative Care
- pain management should be continuous from OR to post-anesthetic care unit (PACU) to hospital ward and home

Common Post-Operative Anesthetic Complications

Nausea and Vomiting
- hypotension and bradycardia must be ruled out
- pain and surgical manipulation also cause nausea
- often treated with dimenhydrinate (Gravol®), metoclopramide (Maxeran®; not with bowel obstruction), prochlorperazine (Stemetil®), ondansetron (Zofran®), granisetron (Kytril®)

Confusion and Agitation
- ABCs first – confusion or agitation can be caused by airway obstruction, hypercapnea, hypoxemia
- neurologic status (Glasgow Coma Scale, pupils), residual paralysis from anesthetic
- pain, distended bowel/bladder
- fear/anxiety/separation from caregivers, language barriers
- metabolic disturbance (hypoglycemia, hypercalcemia, hyponatremia – especially post-TURP)
- intracranial cause (stroke, raised intracranial pressure)
- drug effect (ketamine, anticholinergics)
- elderly patients are more susceptible to post-operative delirium

Respiratory Complications
- susceptible to aspiration of gastric contents due to PONV and unreliable airway reflexes
- airway obstruction (secondary to reduced muscle tone from residual anesthetic, soft tissue trauma and edema, or pooled secretions) may lead to inadequate ventilation, hypoxemia, and hypercapnia
- airway obstruction can often be relieved with head tilt, jaw elevation, and anterior displacement of the mandible. If the obstruction is not reversible, a nasal or oral airway may be used

Hypotension
- must be identified and treated quickly to prevent inadequate perfusion and ischemic damage
- reduced cardiac output (hypovolemia, most common cause) and/or peripheral vasodilation (residual anesthetic agent)
- first step in treatment is usually the administration of fluids ± inotropic agents

Hypertension
- pain, hypercapnia, hypoxemia, increased intravascular fluid volume, and sympathomimetic drugs can cause HTN
- sodium nitroprusside or beta-blocking drugs (e.g. esmolol and metoprolol) can be used to treat HTN

Risk Factors for Post-Operative Nausea and Vomiting (PONV)
- Young age
- Female
- History of PONV
- Non-smoker
- Type of surgery: ophtho, ENT, abdo/pelvic, plastics
- Type of anesthetic: N2O, opioids, volatile agents

Drugs for Preventing Post-Operative Nausea and Vomiting
Cochrane DB Syst Rev 2006;3:CD004125
Purpose: To evaluate the efficacy of antiemetics in preventing PONV.
Methods: A meta-analysis was performed looking at randomized controlled trials comparing an antiemetic to either a second antiemetic or placebo. Trials looking at dosing and/or timing of medication administration were also included. PONV was used as the primary outcome.
Results: 737 studies involving 103,237 patients. Eight drugs significantly reduced the occurrence of PONV, namely: droperidol, metoclopramide, ondansetron, tropisetron, dolasetron, dexamethasone, cyclizine, and granisetron. Relative risk (RR) vs. placebo varied between 0.60-0.80. Side effects included a significant increase in drowsiness for droperidol (RR 1.32) and headache for ondansetron (RR 1.16). The cumulative number needed to treat was 3.57.
Conclusion: Antiemetic medication is effective for reducing the occurrence of PONV. However, further investigation needs to be done to determine whether antiemetics can cause more severe (and likely rare) side effects, which could alter how liberally they are used.
**Pain Management**

**Definitions**
- pain: perception of nociception, which occurs in the brain
- nociception: detection, transduction, and transmission of noxious stimuli

**Pain Classifications**
- temporal: acute vs. chronic
- mechanism: nociceptive vs. neuropathic

**Acute Pain**
- pain of short duration (<6 wk) usually associated with surgery, trauma, or acute illness; often associated with inflammation
- usually limited to the area of damage/trauma and resolves with healing

---

**Pharmacological Management of Acute Pain**
- ask the patient to rate the pain out of 10, or use visual analog scale, to determine severity
- pharmacological treatment guided by WHO analgesia ladder
- patient controlled analgesia (PCA)
  - involves the use of computerized pumps that can deliver a constant infusion as well as bolus breakthrough doses of parenterally-administered opioid analgesics
  - limited by lockout intervals
  - most commonly used agents: morphine and hydromorphone
- see Table 13, A28 for suggested infusion rate, PCA dose and lockout intervals

**Table 10. Commonly Used Analgesics**

**Cautionary Use of NSAIDs in Patients with:**
- Asthma
- Coagulopathy
- GI ulcers
- Renal insufficiency
- Pregnancy, 3rd trimester

**Common Side Effects of Opioids**
- N/V
- Constipation
- Sedation
- Pruritus
- Abdominal pain
- Urinary retention
- Respiratory depression

When prescribing opioids, consider:
- Breakthrough dose
- Anti-emetics
- Laxative

**PCA Parameters**
- Loading dose
- Bolus dose
- Lockout interval
- Continuous infusion (optional)
- Maximum 4 h dose (limit)

**Advantages of PCA**
- Improved patient satisfaction
- Fewer side effects
- Accommodates patient variability
- Accommodates changes in opioid requirements
Physiologic Changes in Pregnancy

- Airway
  - possible difficult airway as tissues becomes edematous and friable especially in labor
- Respiratory
  - decreased FRC and increased O₂ consumption → desaturation occurs more quickly during anesthesia
- Cardiovascular system
  - increased blood volume > increased RBC mass → mild anemia
  - decreased SVR proportionately greater than increased CO → decreased BP
  - prone to decreased BP due to aortocaval compression – therefore for surgery, a pregnant patient is positioned in left uterine displacement using a wedge under her right flank
- Central nervous system
  - decreased MAC due to hormonal effects
  - increased block height due to engorged epidural veins
- Gastrointestinal system
  - delayed gastric emptying
  - increased volume and acidity of gastric fluid
  - decreased LES tone
  - increased abdominal pressure
  - combined, these lead to an increased risk of aspiration – therefore for surgery, a pregnant patient is given sodium citrate 30 cc PO immediately before surgery to neutralize gastric acidity

Opioid Antagonists (naloxone, naltrexone)

- indication: opioid overdose (manifests primarily at CNS, e.g. respiratory depression)
- mechanism of action: competitively inhibit opioid receptors, predominantly µ receptors
  - naloxone is short-acting (t½ = 1 h); effects of narcotic may return when naloxone wears off; therefore, the patient must be observed closely following its administration
  - naltrexone is longer-acting (t½ = 10 h); less likely to see return of opioid effects
- Side Effects/Toxicity
  - Gastric ulceration/bleeding
  - Decreased renal perfusion
  - Photosensitivity
  - Premature closure of the ductus arteriosus in pregnancy
  - Respiratory depression
  - Constipation and abdominal pain
  - Sedation
  - N/V
  - Pruritus
  - Confusion (particularly in the elderly)
  - Dependence

Neuropathic Pain

- pain caused by peripheral or central nervous system injury, often described as burning, lancinating, shooting, or tingling
- results in allodynia (pain in response to normally painless stimuli) or hyperalgesia (increased sensitivity to painful stimuli)
- consider adding anticonvulsants (gabapentin, pregabalin) or low-dose tricyclic antidepressant as opioids are ineffective

Chronic Pain

- chronic pain: greater than 3 mo, or recurrent pain that occurs at least 3 times throughout three month period
- pain of duration or intensity that persists beyond normal tissue healing and adversely affects functioning
- may have nociceptive and neuropathic components; dysregulation of analgesic pathways implicated
- in the perioperative period, consider continuing regular long-acting analgesics and augmenting with regional techniques, adjuvants, additional opioid analgesia, and non-pharmacological techniques

Obstetrical Anesthesia

Patient Controlled Opioid Analgesia vs. Conventional Opioid Analgesia for Post-Operative Pain

Cochrane Database Syst Rev 2006;4:CD003348

Purpose: To evaluate the efficacy of patient controlled analgesia (PCA) as compared to conventional as-needed analgesia administration providing pain relief in post-operative patients.

Methods: Meta-analyses of randomized controlled trials comparing PCA vs. conventional administration of opioid analgesia. Assessment employed a visual analog scale (VAS) for pain intensity along with overall analgesic consumption, patient satisfaction, length of stay, and adverse side effects.

Results: 55 studies with a total of 2,023 patients receiving PCA and 1,838 patients with standard as-needed opioid administration. PCA provided significantly better pain control through 72 h post-operatively, but patients consumed significantly more opioids (> 7 mg morphine/24 h, p < 0.05). Significantly more patients reported pruritus in the PCA group compared to controls with a number needed to harm of 13. No significant difference in overall length of stay in hospital, sedation level, N/V, or urinary retention.

Conclusions: PCA is more effective than standard as-needed administration for reducing post-operative pain. However, patients using PCA consume more opioids overall, and have more pruritus.

The Effect of Epidural Analgesia on Labor, Maternal, and Neonatal Outcomes: A Systematic Review

Am J Obstet Gynecol 2002;186:S69-77

Study: Meta-analysis of 14 studies with 4,324 women.

Selection Criteria: RCTs and prospective cohort studies between 1980-2001 comparing epidural analgesia to parenteral opioid administration during labor.

Types of Participants: Healthy women with uneventful pregnancies.

Intervention: Participants were randomized to either epidural analgesia or parenteral opioid administration during labor.

Outcomes and Results: Maternal – there were no differences between the 2 groups in first-stage labor length, incidence of Cesarean delivery, incidence of instrumented vaginal delivery for dystocia, nausea, or mid-to-low back pain post-partum. However, second-stage labor length was longer (mean=15 min) and there were greater reports of lower and hypertension in the epidural group. Also, lower pain scores and greater satisfaction with analgesia were reported among the epidural group. There was no difference in lactation success at 6 wk and urinary incontinence was more frequent in the epidural group immediately post-partum, but not at 3 mo or 1 yr (evidence from PC studies only).

Neonatal – there were no differences between the 2 groups for incidence of fetal heart rate abnormalities, intrapartum meconium, poor 5-min Apgar score, or low umbilical artery pH. However, the incidence of poor 1-min Apgar scores and need for neonatal naloxone were higher in the parenteral opioid group.

Conclusions: Epidural analgesia is a safe intrapartum method for labor pain relief and women should not avoid epidural analgesia for fear of neonatal harm. Cesarean delivery, breastfeeding difficulties, long-term back pain, or long-term urinary incontinence.
Options for Analgesia during Labor

• Psychoprophylaxis – Lamaze method
  ▪ patterns of breathing and focused attention on fixed object
• Systemic medication
  ▪ easy to administer, but risk of maternal or neonatal depression
  ▪ opioids most commonly used if delivery is not expected within 4 h
• Inhalational analgesia
  ▪ easy to administer, makes uterine contractions more tolerable, but does not relieve pain completely
  ▪ 50% nitrous oxide
• Neuraxial anesthesia
  ▪ provides excellent analgesia with minimal depressant effects
  ▪ hypotension is the most common complication
  ▪ maternal BP monitored q2-5 min for 15-20 min after initiation and regularly thereafter
  ▪ epidural usually given as it preferentially blocks sensation, leaving motor function intact

Options for Caesarean Section

• neuraxial: spinal or epidural
• general: used if contraindications or time precludes regional blockade

Pediatric Anesthesia

Respiratory System

• in comparison to adults, anatomical differences in infants include:
  ▪ large head, short trachea/neck, large tongue, adenoids, and tonsils
  ▪ narrow nasal passages (obligate nasal breathers until 5 mo)
  ▪ narrowest part of airway at the level of the cricoid vs. glottis in adults
  ▪ epiglottis is longer, U shaped and angled at 45 degrees; carina is wider and is at the level of T2 (T4 in adults)
• physiologic differences include
  ▪ faster RR, immature respiratory centers which are depressed by hypoxia/hypercapnea
  ▪ less oxygen reserve during apnea – decreased total lung volume, vital and functional reserve capacity together with higher metabolic needs
• greater V/Q mismatch – lower lung compliance due to immature alveoli (mature at 8 yr)
  ▪ greater work of breathing – greater chest wall compliance, weaker intercostals/diaphragm, and higher resistance to airflow

Cardiovascular System

• blood volume at birth is approximately 80 mL/kg; transfusion should be started if >10% of blood volume lost
• children have a high HR and low BP
• CO is dependent on HR, not stroke volume because of low heart wall compliance; therefore, bradycardia → severe compromise in CO

Temperature Regulation

• vulnerable to hypothermia
• minimize heat loss by use of warming blankets, covering the infant's head, humidification of inspired gases, and warming of infused solutions

Central Nervous System

• MAC of halothane is increased compared to the adult (0.75% adult, 1.2% infant, 0.87% neonate)
• NMJ is immature for the first 4 wk of life and thus there is an increased sensitivity to non-depolarizing relaxants
• parasympathetics mature at birth, sympathetics mature at 4-6 mo → autonomic imbalance
• infant brain is 12% of body weight and receives 34% of CO (adult: 2% body weight and 14% CO)

Glucose Maintenance

• infants less than 1 yr old can become seriously hypoglycemic during pre-operative fasting and post-operatively if feeding is not recommenced as soon as possible
• after 1 yr, children are able to maintain normal glucose homeostasis in excess of 8 h

Pharmacology

• higher dose requirements because of higher TBW (75% vs. 60% in adults) and greater volume of distribution
• barbiturates/opioids more potent due to greater permeability of BBB
• muscle relaxants

To increase alveolar minute ventilation in neonates, increase respiratory rate, not tidal volume.

Neonate: 30-40 breaths/min
Age 1-13: (24 – [age/2]) breaths/min
Uncommon Complications

Malignant Hyperthermia

- hypermetabolic disorder of skeletal muscle due to an uncontrolled increase in intracellular Ca\(^{2+}\)
- pathogenesis: Genetic anomaly (autosomal dominant) of ryanodine receptor which regulates the Ca\(^{2+}\) channel in the sarcoplasmic reticulum of skeletal muscle
- incidence of 1-5 per 100,000; may be associated with skeletal muscle abnormalities such as dystrophy or myopathy
- anesthetic drugs triggering MH include:
  - all inhalational agents except nitrous oxide
  - depolarizing muscle relaxant – SCh

Clinical Picture
- onset: immediate or hours after contact with trigger agent
  - increased oxygen consumption
  - increased ETCO\(_2\) on capnograph
  - tachycardia/dysrhythmia
  - tachypnea/cyanosis
  - diaphoresis
  - HTN
  - increased temperature (late sign)
- muscular symptoms
  - trismus (masseter spasm) common but not specific for MH (occurs in 1% of children given SCh with halothane anesthesia)
  - tender, swollen muscles due to rhabdomyolysis
  - trunk or total body rigidity

Complications
- coma
- DIC
- rhabdomyolysis
- myoglobinuric renal failure/hepatic dysfunction
- electrolyte abnormalities (e.g. hyperkalemia) and secondary arrhythmias
- ARDS
- pulmonary edema
- can be fatal if untreated

Prevention
- suspect MH in patients with a family history of problems/death with anesthetic
- avoid all trigger medications, use vapour free equipment, use regional anesthesia if possible
- central body temp and ET\(_{CO_2}\) monitoring

Malignant Hyperthermia Management (Based on Malignant Hyperthermia Association of the U.S. [MHAUS] Guidelines, 2008)
1. notify surgeon, discontinue volatile agents and succinylcholine, hyperventilate with 100% oxygen at flows of 10 L/min or more, halt the procedure as soon as possible
2. dantrolene 2.5 mg/kg IV, through large-bore IV if possible
3. repeat until there is control of signs of MH; sometimes up to 30 mg/kg is necessary
4. cool patients with core temperature >39°C
  - lavage open body cavities, stomach, bladder, rectum; apply ice to surface; infuse cold saline IV
  - stop cooling if temperature is <38°C to prevent drift to <36°C
5. dysrhythmias usually respond to treatment of acidosis and hyperkalemia
  - use standard drug therapy except Ca\(^{2+}\) channel blockers as they may cause hyperkalemia and cardiac arrest in presence of dantrolene

ETT Sizing in Pediatrics
Diameter (mm) of tracheal tube in children after 1 year = (age/4) + 4
Length (cm) of tracheal tube = (age/2) + 12

Signs of Malignant Hyperthermia
- Unexplained rise in ETCO\(_2\)
- Increase in minute ventilation
- Tachycardia
- Rigidity
- Hyperthermia (late sign)

Basic Principles of MH Management
“Some Hot Dude Better Get Iced Fluids Fast”
Stop all triggering agents, give 100% O\(_2\)
Hyperventilate
Dantrolene 2.5 mg/kg every 5 min
Bicarbonate
Glucose and insulin
IV fluids; cool patient to 38°C
Fluid output; consider furosemide
Tachycardia: be prepared to treat VT
6. hyperkalemia
   ▪ treat with hyperventilation, bicarbonate, glucose/insulin, calcium
   ▪ bicarbonate 1-2 mEq/kg IV, calcium chloride 10 mg/kg or calcium gluconate 10-50 mg/kg
   for life-threatening hyperkalemia and check glucose levels hourly
7. follow ETCO2, electrolytes, blood gases, creatine kinase (CK), core temperature, urine output/color with Foley catheter, coagulation studies
   ▪ if CK and/or potassium rises persistently or urine output falls to <0.5 mL/kg/h, induce diuresis to >1 mL/kg/h urine to avoid myoglobinuric renal failure
8. maintain anesthesia with benzodiazepines, opioids, and propofol
9. transfer to ICU bed

Abnormal Pseudocholinesterase

- pseudocholinesterase hydrolyzes SCh and mivacurium
- individuals with abnormal pseudocholinesterase will have prolonged muscular blockade
- SCh and mivacurium are contraindicated in those with abnormal pseudocholinesterase
- if SCh or mivacurium are given accidentally, treat with mechanical ventilation until function returns to normal (do not use cholinesterase inhibitors)

</table>

**Coronary steal: sevoflurane causes small vessel dilation which may compromise blood flow to areas of the heart with fixed perfusion (e.g. stents, atherosclerosis)**
### Table 15. Depolarizing Muscle Relaxants (Non-Competitive): Succinylcholine (SCh)

**Mechanism of Action**
Mimics ACh and binds to ACh receptors causing prolonged depolarization; initial fasciculation may be seen, followed by temporary paralysis secondary to blocked ACh receptors by SCh.

**Intubating Dose**
1-1.5 mg/kg

**Onset**
30-60 s – RAPID (fastest of all muscle relaxants)

**Duration**
3-5 min – SHORT (no reversing agent for SCh)

**Metabolism**
SCh is hydrolyzed by plasma cholinesterase (pseudocholinesterase), found only in plasma and not at the NMJ.

**Indications**
- Assist intubation
- Increased risk of aspiration (need rapid paralysis and airway control)
- Short procedures (e.g. full stomach), hiatus hernia, obesity, pregnancy, trauma
- Electroconvulsive therapy (ECT)
- Laryngospasm

**Side Effects**
1. SCh also stimulates muscarinic cholinergic autonomic receptors (in addition to nicotinic receptors)
   - May cause bradycardia, dysrythmias, sinus arrest, increased secretions of salivary glands (especially in children)
2. Hyperkalemia
   - Disruption of motor nerve activity causes proliferation of extrajunctional (outside NMJ) cholinergic receptors
   - Depolarization of an increased number of receptors by SCh may lead to massive release of potassium out of muscle cells
   - Patients at risk:
     - 3rd degree burns 24 h-6 mo after injury
     - Traumatic paralysis or neuromuscular diseases (e.g. muscular dystrophy)
     - Severe intra-abdominal infections
     - Severe closed head injury
     - Upper motor neuron lesions
3. Can trigger MH
4. Increased ICP/intraocular pressure/intragastric pressure (no increased risk of aspiration if competent lower esophageal sphincter)
5. Fasciculations, post-operative myalgia – may be minimized if small dose of non-depolarizing agent given before SCh administration

**Contraindications**

| Absolute | Known hypersensitivity or allergy, positive history of malignant hyperthermia, myotonia (m. congenita, m. dystrophica, paramyotonia congenital), high risk for hyperkalemia response |
| Relative | Known history of plasma cholinesterase deficiency, myasthenia gravis, myasthenic syndrome, familial periodic paralysis, open eye injury |

### Table 16. Non-Depolarizing Muscle Relaxants (Competitive)

**Mechanism of Action**
Competitive blockade of postsynaptic ACh receptors preventing depolarization.

Advanced Cardiac Life Support (ACLS) Guidelines

Figure 16. Adult cardiac arrest algorithm
**Adult Tachycardia (With Pulse)**

1. **Assess appropriateness for clinical condition**
   Heart rate typically ≥150/min if tachyarrhythmia

2. **Identify and treat underlying cause**
   - Maintain patent airway; assist breathing as necessary
   - Oxygen (if hypoxemic)
   - Cardiac monitor to identify rhythm; monitor blood pressure and oximetry

3. **Persistent tachyarrhythmia causing:**
   - Hypotension?
   - Acutely altered mental status?
   - Signs of shock?
   - Ischemic chest discomfort?
   - Acute heart failure?

4. **Synchronized cardioversion**
   - Consider sedation
   - If regular narrow complex, consider adenosine

5. **Wide QRS? ≥0.12 second**
   - No
   - IV access and 12-lead ECG if available
   - Vagal maneuvers
   - Adenosine (if regular)
   - β-Blockers or calcium channel blocker
   - Consider expert consultation

6. **Monitor and observe**
   - Yes
   - IV access and 12-lead ECG if available
   - Consider adenosine only if regular and monomorphic
   - Consider antiarrhythmic infusion
   - Consider expert consultation

**Doses/Details**

**Synchronized Cardioversion**
- Initial recommended doses:
  - Narrow regular: 50-100 J
  - Narrow irregular: 120-200 J monophasic
  - Wide regular: 100 J
  - Wide irregular: defibrillation dose (NOT synchronized)

**Adenosine IV Dose:**
- First dose: 6 mg rapid IV push; follow with NS flush
- Second dose: 12 mg if required

**Antiarrhythmic Infusions for Stable Wide-QRS Tachycardia**
- **Procainamide IV Dose:**
  - 20-50 mg/min until arrhythmia suppressed, hypotension ensues, QRS duration increases ≥50%, or maximum dose 17 mg/kg given
  - Maintenance infusion: 1-4 mg/min
  - Avoid if prolonged QT or CHF

- **Sotalol IV Dose:**
  - 100 mg (1.5 mg/kg) over 5 min
  - Avoid if prolonged QT

**Figure 17. Adult tachycardia algorithm**

---

**Adult Bradycardia (With Pulse)**

1. **Assess appropriateness for clinical condition**
   Heart rate typically <50/min if bradyarrhythmia

2. **Identify and treat underlying cause**
   - Maintain patent airway; assist breathing as necessary
   - Oxygen (if hypoxemic)
   - Cardiac monitor to identify rhythm; monitor blood pressure and oximetry
   - IV access
   - 12-Lead ECG if available; do not delay therapy

3. **Persistent bradyarrhythmia causing:**
   - Hypotension?
   - Acutely altered mental status?
   - Signs of shock?
   - Ischemic chest discomfort?
   - Acute heart failure?

4. **Monitor and observe**
   - No

5. **Atropine**
   - If atropine ineffective:
     - Transcutaneous pacing OR
     - Dopamine infusion OR
     - Epinephrine infusion

6. **Consider:**
   - Expert consultation
   - Transvenous pacing

**Doses/Details**

**Atropine IV Dose:**
- First dose: 0.5 mg bolus
- Repeat every 3-5 min
- Max: 3 mg

**Dopamine IV Infusion:**
- 2-10 µg/kg/min

**Epinephrine IV Infusion:**
- 2-10 µg/min

**Figure 18. Adult bradycardia algorithm**

Basic Anatomy Review

Coronary Circulation

- conventional arterial supply to the heart arises from the right and left coronary arteries, which originate from the root of the aorta
  - right coronary artery (RCA)
    - acute marginal branches
    - atrioventricular (AV) nodal artery
    - posterior interventricular artery (PIV) = posterior descending artery (PD)
  - left main coronary artery (LCA): two major branches
    - left anterior descending artery (LAD)
      - septal branches
      - diagonal branches
    - left circumflex artery (LC)
      - obtuse marginal branches
- dominance of circulation
  - right-dominant circulation: PIV and at least one posterolateral branch arise from RCA (80%)
  - left-dominant circulation: PIV and at least one posterolateral branch arise from LC (15%)
  - balanced circulation: dual supply of posteroinferior LV from RCA and LC (5%)
- the sinoatrial (SA) node is supplied by the SA nodal artery, which may arise from the RCA (60%) or LCA (40%)
- most venous blood from the heart drains into the RA through the coronary sinus, although a small amount drains through thebesian veins into all four chambers, contributing to the physiologic R-L shunt

Figure 1. Anatomy of the coronary arteries (right anterior oblique projection)
Cardiac Anatomy

- layers of the heart
  - endocardium
  - myocardium
  - epicardium
  - visceral pericardium
  - pericardial cavity
  - parietal pericardium

- valves
  - semilunar valves: no subvalvular apparatus present
    - aortic valve, 3 valve leaflets: separates LV and ascending aorta
    - pulmonic valve, 3 valve leaflets: separates RV and main pulmonary artery (PA)
  - atrioventricular valves: subvalvular apparatus present in the form of chordae tendinae and papillary muscles
    - tricuspid valve, 3 valve leaflets: separates RA and RV
    - mitral valve, 2 valve leaflets: separates LA and LV

- conduction system
  - SA node governs pacemaking control
  - anterior-, middle-, and posterior-internal nodal tracts carry impulses in the right atrium and along Bachmann's bundle in the left atrium
  - atrial impulses converge at the AV node
    - the AV node is the only conducting tract from the atria to the ventricles because of electrical isolation by the annulus fibrosis (except when accessory pathways are present)
  - the bundle of His bifurcates into left and right bundle branches (LBB and RBB)
  - LBB further splits into anterior and posterior fascicles
  - RBB and fascicles of LBB give off Purkinje fibers which conduct impulses into the ventricular myocardium

---

Figure 2a. Cardiac cycle
They gray shaded bars indicate isovolumic contraction (left) and isovolumic relaxation (right).

Figure 2b. JVP waveform

Legend:
- AV – aortic valve
- LA – left atrium
- LV – left ventricle
- MV – mitral valve

Figure 3. Conduction system of the heart

Figure 4. Blood vessel structure

Features of Abnormal JVP Wave Formation
- Atrial fibrillation: absent a wave
- 3rd degree heart block: cannon a waves
- Tricuspid regurgitation: cv wave, elevated JVP
- Cardiac tamponade: x descent only, absent y descent
- Constrictive pericarditis: prominent y descent, Kussmaul's sign (paradoxical increase in JVP with inspiration)
cardiovascular innervation
  - sympathetic nerves
    - innervate the SA node, AV node, ventricular myocardium and vasculature
    - SA node (β1) fibers increase pacemaking activity (chronotropy)
    - cardiac muscle (β1) fibers increase contractility (inotropy) to help increase cardiac output
    - stimulation of β1- and β2-receptors in the skeletal and coronary circulation causes vasodilatation
  - parasympathetic nerves
    - innervate the SA node, AV node, atrial myocardium but few vascular beds
    - basal vagal tone dominates the tonic sympathetic stimulation of the SA node and AV node resulting in slowing of pacemaker activity and conduction (i.e. reduced dromotropy – if only affecting AV node conduction)
    - parasympathetics have very little impact on total peripheral vascular resistance

Differential Diagnoses of Common Presentations

Chest Pain
- cardiac
  - MI/angina
  - myocarditis
  - pericarditis/Dressler’s syndrome
  - cardiac tamponade
- pulmonary
  - pneumonia
  - PE
  - pneumothorax/hemothorax, tension pneumothorax
  - empyema
  - pulmonary neoplasm
  - bronchiecstasy
  - TB
- gastrointestinal
  - esophageal: spasm, GERD, esophagitis, ulceration, achalasia, neoplasm, Mallory-Weiss syndrome, esophageal rupture
- gastrointestinal
  - PUD
  - gastritis
  - pancreatitis
  - biliary colic
  - mediastinal
    - lymphoma
    - thymoma
  - vascular
    - dissecting aortic aneurysm
    - aortic rupture
    - surface structures
      - costochondritis
      - rib fracture
      - skin (bruising, herpes zoster)
      - breast
    - anxiety/psychosomatic

Loss of Consciousness
- hypovolemia
- cardiac
  - structural or obstructive causes
    - ACS
    - AS
    - HCM
    - cardiac tamponade, constrictive pericarditis
    - arrhythmias (see Arrhythmias, C15)
- respiratory
  - massive pulmonary embolism
  - pulmonary HTN
  - hypoxia
  - hypercapnia
  - neurologic
  - stroke/TIA (esp. vertebrobasilar insufficiency)
  - migraine
  - seizure
  - metabolic
    - anemia
    - hypoglycemia
  - drugs
    - antihypertensives
    - antiarrhythmics
    - diuretics
  - vasovagal
    - autonomic dysfunction
    - diabetic neuropathy
    - psychiatric
    - panic attack

Local Edema
- inflammation/infection
- venous or lymphatic obstruction
  - thrombophlebitis/deep vein thrombosis
  - venous insufficiency
  - chronic lymphangitis
  - lymphatic tumor infiltration
  - filariasis

Generalized Edema
- increased hydrostatic pressure/fluid overload
  - heart failure
  - pregnancy
  - drugs (e.g. CCBs)
  - iatrogenic (e.g. IV fluids)
  - decreased oncotic pressure/hypoalbuminemia
  - nephrotic syndrome
- liver cirrhosis
- malnutrition
- increased capillary permeability
- severe sepsis
- hormonal
  - hypothyroidism
  - exogenous steroids
- pregnancy
- estrogens
Palpitations

- cardiac
  - arrhythmias (PAC, PVC, SVT, VT)
  - valvular heart disease
  - HCM
- endocrine
  - thyrotoxicosis
  - pheochromocytoma
  - hypoglycemia
- systemic
  - fever
  - anemia
- drugs
  - stimulants and anticholinergics
- psychiatric
  - panic attack

Dyspnea

- cardiovascular
  - acute MI
  - CHF/LV failure
  - aortic/mitral stenosis
  - aortic/mitral regurgitation
  - arrhythmia
  - cardiac tamponade
  - restrictive pericarditis
  - left-sided obstructive lesions (e.g. left atrial myxoma)
  - elevated pulmonary venous pressure
- respiratory
  - airway disease
    - asthma
  - COPD exacerbation
  - upper airway obstruction (anaphylaxis, foreign body, mucus plugging)
  - parenchymal lung disease
    - ARDS
  - pneumonitis
  - interstitial lung disease
  - pulmonary vascular disease
    - PE
  - pulmonary HTN
  - pulmonary vasculitis
  - pleural disease
    - pneumothorax
  - pleural effusion
  - neuromuscular and chest wall disorders
    - C-spine injury
  - polynysoitis, myasthenia gravis, Guillain-Barré syndrome
  - kyphoscoliosis
  - anxiety/psychosomatic
    - hemorrhagic/metabolic
      - anemia, acidosis, hypercapnia

Cardiac Diagnostic Tests

Electrocardiography Basics

- the electrocardiogram (ECG) is a graphic representation of the electrical activity of the heart recorded from the surface of the body
- on the ECG graph
  - the horizontal axis represents time (at usual paper speed 25 mm/s)
    - 1 mm (1 small square) = 40 msec
    - 5 mm (1 large square) = 200 msec
  - the vertical axis represents voltage (at usual standard gain setting)
    - 1 mm (1 small square) = 0.1 mV
    - 10 mm (2 large squares) = 1 mV
- leads
  - standard 12-lead ECG
    - limb leads: I, II, III, aVL, aVR, aVF
    - precordial leads: V1-V6 (V1-V2 septal, V3-V4 anterior, V5-V6 lateral)
  - additional leads
    - right-sided leads: V3R-V6R (useful in RV infarction and dextrocardia)
  - lateral = I, aVL, V5, V6; inferior = II, III, aVF; anterior = V1-V4

Approach to ECGs

Introduction
Historically, the electrocardiogram has been a tricky subject for medical students. For many years, the classical approach has been taught in medical schools, which has demystified the ECG. Below, we are presenting both the Classical Approach and the newer PQRSTU Approach to provide students with different ways to view the ECG. Despite methodological differences, the rigor and final result is the same. These two approaches should help you better understand the concepts of ECG interpretation and equip you with the necessary skills to interpret ECGs in exam scenarios and clinical practice.

Classical Approach to ECGs

RATE
- normal = 60-100 bpm (atrial rate: 150-250 bpm = paroxysmal tachycardia, 250-350 bpm = atrial flutter, >350 bpm = AFib)
- regular rhythm
  - to calculate the rate, divide 300 by number of large squares between 2 QRS complexes (there are 300 large squares in 1 min: 300 x 200 msec = 60 s)
or remember 300-150-100-75-60-50-43 (rate falls in this sequence with the number of large squares between 2 QRS complexes)

- irregular rhythm
  - rate = 6 x number of R-R intervals in 10 s (the “rhythm strips” are 10 s recordings)
  - types: wandering pacemaker, multifocal atrial tachycardia, AFib
  - atrial escape = 60-80 bpm; junctional escape = 40-60 bpm; ventricular escape = 20-40 bpm

**RHYTHM**

- regular: R-R interval is the same across the tracing
- irregular: R-R interval varies across the tracing
- regularly irregular: repeating pattern of varying R-R intervals
- irregularly irregular: R-R intervals vary erratically
- normal sinus rhythm (NSR)
  - P wave precedes each QRS; QRS follows each P wave
  - P wave axis is normal (positive in leads I, aVF)
  - rate between 60-100 bpm

**AXIS**

- mean axis indicates the direction of the mean vector
- can be determined for any waveform (P, QRS, T)
- the standard ECG reported QRS axis usually refers to the mean axis of the frontal plane – it indicates the mean direction of ventricular depolarization forces
- QRS axis in the frontal plane
  - normal axis: -30º to 90º (i.e. positive QRS in leads I and II)
  - left axis deviation (LAD): axis <-30º
  - right axis deviation (RAD): axis >90º
- QRS axis in the horizontal plane is not routinely calculated – it is directed posteriorly and to the left
  - transition from negative to positive is usually in lead V3

**Table 1. Conduction Abnormalities**

<table>
<thead>
<tr>
<th>Left Bundle Branch Block (LBBB)</th>
<th>Right Bundle Branch Block (RBBB)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Complete LBBB</td>
<td>Complete RBBB</td>
</tr>
<tr>

</tbody>
</table>

**Left Anterior Fascicular Block (LAFB)**

<table>
<thead>
<tr>
<th>Left Anterior Hemiblock</th>
<th>Left Posterior Fascicular Block (LPFB)</th>
<th>Bifascicular Block</th>
</tr>
</thead>
<tbody>
<tr>
<td>Left Axis Deviation (-30º to -90º)</td>
<td>Right Axis Deviation (110º to 180º)</td>
<td>RBBB pattern</td>
</tr>
<tr>
<td>Small q and prominent R in leads I and aVl</td>
<td>Small r and prominent S in leads II, III, and aVl</td>
<td>Small q and prominent R</td>
</tr>
<tr>
<td>Small r and prominent S in leads II, III, and aVl</td>
<td>Small q and prominent R in leads II, III, and aVl</td>
<td>The first 60 msec (1.5 small squares) of the QRS shows the pattern of LAFB or LPFB</td>
</tr>
<tr>
<td>RBBB pattern refers to impaired conduction in two of the three fascicles, most commonly a RBBB and left anterior hemiblock; the appearance on an ECG meets the criteria for both types of blocks</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Nonspecific Intraventricular Block**

- QRS duration >120 msec
- absence of criteria for LBBB or RBBB
Table 2. Hypertrophy/Chamber Enlargement

Left Ventricular Hypertrophy (LVH) | Right Ventricular Hypertrophy (RVH)
--- | ---
• S in V1 + R in V5 or V6 > 35 mm above age 40, (>40 mm for age 31-40, >45 mm for age 21-30)  
• R in aVL > 11 mm  
• R in I + S in III > 25 mm  
• Additional criteria:  
  ▪ LV strain pattern (ST depression and T wave inversion in leads I, aVL, V4-V6)  
  ▪ Left atrial enlargement  
• Right axis deviation  
• R/S ratio > 1 or qR in lead V1  
• RV strain pattern: ST segment depression and T wave inversion in leads V1-2

Left Atrial Enlargement (LAE) | Right Atrial Enlargement (RAE)
--- | ---
• Biphasic P wave with the negative terminal component of the P wave in lead V1 ≥ 1 mm wide and ≥ 1 mm deep  
• P wave > 120 msec, notched in lead II (“P mitrale”)  
• P wave > 2.5 mm in height in leads II, III, or aVF (“P pulmonale”)  
• Biphasic P wave with the negative terminal component of the P wave in lead V1 ≥ 1 mm wide and ≥ 1 mm deep  
• P wave > 120 msec, notched in lead II (“P mitrale”)  
• P wave > 2.5 mm in height in leads II, III, or aVF (“P pulmonale”)  
• Additional criteria:  
  ▪ Left atrial enlargement

ISCHEMIA/INFARCTION

• Look for the anatomic distribution of the following ECG abnormalities (see Table 3)
  
  ▪ Ischemia  
    ▪ ST segment depression  
    ▪ T wave inversion (most commonly in V1-V6)
  
  ▪ Injury  
    ▪ Transmural (involving the epicardium)  
      ▪ ST elevation in the leads facing the area injured/infarcted  
      ▪ Transient ST elevation may occur in patients with coronary artery spasm  
        (e.g. Prinzmetal angina) which can be slight or prominent (>10 mm)  
    ▪ Subendocardial  
      ▪ Marked ST depression in the leads facing the affected area  
      ▪ May be accompanied by enzyme changes and other signs of MI  
      ▪ May also occur with angina

Figure 10. Typical ECG changes with infarction

• Evolving infarction (ST elevation in contiguous leads = acute MI)
  
  ▪ “Typical” sequential changes of evolving MI  
    1. Hyperacute T waves (tall, symmetric T waves) in the leads facing the infarcted area, with or without ST elevation
    2. ST elevation (injury pattern) in the leads facing the infarcted area  
      ▪ Usually in the first hours post infarct  
      ▪ In acute posterior infarction, there is depression in V1-V3 (reciprocal to ST elevation in the posterior leads, that are not recorded in the standard 12-lead ECG)  
    3. Significant Q waves: > 40 msec or > 1/3 of the total QRS (hours to days post-infarct)
    4. Inverted T waves (one day to weeks after infarction)  
      ▪ This classical sequence does not always occur  
      ▪ Q waves of infarction may appear in the very early stages, with or without ST changes  
      ▪ Non-Q wave infarction: there may be only ST or T changes despite clinical evidence of infarction
  
  ▪ Completed infarction  
    ▪ Abnormal Q waves (wide Q waves may be found in III and aVL in normal individuals)  
      ▪ Duration > 40 msec (> 30 msec in aVF for inferior infarction)  
      ▪ Q/QRS voltage ratio is > 33%  
    ▪ Abnormal R waves (R/S ratio > 1, duration > 40 msec) in V1 and more frequently in V2 are found in posterior infarction (usually in association with signs of inferior and/or lateral infarction)
Table 3. Areas of Infarction (Q wave)/Ischemia (in right dominant anatomy)

MISCELLANEOUS ECG CHANGES

Electrolyte Disturbances
- hyperkalemia
  - mild to moderate (K⁺ 5-7 mmol/L): tall peaked T waves
  - severe (K⁺ >7 mmol/L): progressive changes whereby P waves flatten and disappear, QRS widens and may show bizarre patterns, axis shifts left or right, ST shift with tall T waves, eventually becomes a “sine wave” pattern
- hypokalemia
  - ST segment depression, prolonged QT interval, low T waves, prominent U waves (U>T)
  - enhances the toxic effects of digitalis
- hypercalcemia
  - shortened QT interval (more extracellular Ca²⁺ means shorter plateau in cardiac action potential)
- hypocalcemia
  - prolonged QT interval (less extracellular Ca²⁺ means longer plateau in cardiac action potential)

![Figure 11. Hyperkalemia](image1)

![Figure 12. Hypokalemia](image2)

Figure 11. Hyperkalemia

Figure 12. Hypokalemia

Hypothermia
- sinus bradycardia
- when severe, prolonged QRS and QT intervals
- AFib with slow ventricular response and other atrial/ventricular dysrhythmias
- Osborne J waves: “hump-like” waves at the junction of the J point and the ST segment

Pericarditis
- early: diffuse ST segment elevation ± PR segment depression, upright T waves
- later: isoelectric ST segment, flat or inverted T waves
- ± tachycardia

Drug Effects
- digitalis
  - therapeutic levels may be associated with “digitalis effect”:
    - ST downsloping or “scooping”
    - T wave depression or inversion
    - QT shortening ± U waves
    - slowing of ventricular rate in AFib
  - toxic levels associated with
    - arrhythmias: paroxysmal atrial tachycardia (PAT) with conduction block, severe bradycardia in AFib, accelerated junctional rhythms, PVCs, ventricular tachycardia (see Arrhythmias, C15)
    - “regularization” of ventricular rate in AFib due to a junctional rhythm and AV dissociation
    - amiodarone, quinidine, phenothiazines, tricyclic antidepressants, antipsychotics, some antihistamines, some antibiotics: prolonged QT interval, U waves

Low Voltage
- Definition: total QRS height in precordial leads <10 mm and/or limb leads <5 mm
- Differential diagnosis
  - Myocardial disease
  - Ischemia
  - Cardiomyopathy (usually infiltrative type), myocarditis
  - Pericardial effusion
  - Thick chest wall/barrel chest: COPD, obesity
  - Generalized edema
  - Hypothyroidism/myxedema
  - Inappropriate voltage standardization

![Figure 13. Osborne J waves of a hypothermic patient](image3)

Digitalis Side Effects
- Palpitations, fatigue, visual changes (yellow vision), decreased appetite, hallucinations, confusion, and depression

Pacemakers
- Demand pacemaker has discharge (narrow vertical spike on ECG strip) prior to widened QRS
- Atrial pacemaker has discharge prior to P wave
- Triggered pacemaker has discharge following the P wave but prior to the widened QRS
- Atrial and ventricular pacing have discharge before the P wave and widened QRS wave
Figure 14. Atrial fibrillation, ST change due to digitalis ("digitalis effect")

Pulmonary Disorders
- cor pulmonale (often secondary to COPD)
  - low voltage, RAD, poor R wave progression
  - RAE and RVH with strain
  - multifocal atrial tachycardia (MAT)
- massive PE
  - sinus tachycardia and AFib/atrial flutter are the most common arrhythmias
  - RAD, RVH with strain – most specific sign is S1Q3T3 (S in I, Q and inverted T wave in III)

Alternative PQRSTU Approach to ECGs

Note: The information seen in this alternative approach – the PQRSTU Approach – is the same as the information in the Classical Approach. It is just organized in a slightly different way based on the Anatomy of the ECG.

Figure 15. ECG correlations with heart activity

P WAVE
- the P wave provides a view into the atria of the heart and represents atrial contraction
- the best leads to view the P waves are II and V1
- assess the P waves for rate (based on the P-P interval relative to the R-R interval), rhythm (rounded, flutter/sawtooth, fibrillation) and axis
- lead II: the P wave should be rounded, <120 msec and <2.5 mm in height
- lead V1: the P wave is biphasic with a negative phase slightly greater than the positive phase
Common P Wave Pathology
- atrial flutter: sawtooth P wave (HINT: flip the ECG upside-down to see it better if unclear)
- atrial fibrillation: absent P wave, may have fibrillatory wave, irregular rhythm
- right atrial enlargement: tall P wave (>2.5 mm) in II or V1 (P pulmonale)
- left atrial enlargement: negative deflection >1 mm deep or >1 mm wide in V1, wide (>120 msec) notched P wave in II (P mitrale)

P-R INTERVAL
- the P-R interval shows the delay between atrial and ventricular contraction that is mediated by the AV node; the magnitude of the delay is referred to as “dromotropy”
- positive dromotropy increases conduction velocity (e.g. epinephrine stimulation), negative dromotropy decreases velocity (e.g. vagal stimulation)
- P-R interval should be 120-200 msec
- long P-R interval (>200 msec)
  - heart block: first degree (fixed, prolonged P-R interval), second degree Mobitz I/Wenckebach (steadily prolonging to eventual dropped beat)
  - heart block
    - first degree: fixed, prolonged P-R interval
    - second degree Mobitz I/Wenckebach: steadily prolonging P-R interval to eventual dropped beat
    - second degree Mobitz II/Hay: fixed P-R interval with ratio of beat to dropped beat (e.g. for every 3 beats, there is one dropped beat [3:1])
  - third degree/complete: variable P-R intervals, P-P and R-R intervals individually constant but not in sync
  - atrial flutter
  - sinus bradycardia (normal to have long P-R if heart rate slow)
  - hypokalemia
  - trifascicular block
- short P-R interval (<120 msec)
  - pre-excitation syndrome (delta wave: upswooping of the P-R segment into the QRS complex indicating pre-excitation)
  - accessory pathways
  - WPW

QRS COMPLEX
- the QRS is where ventricular contraction is visualized
- rate: check the R-R interval to see if it matches the PP interval
- amplitude: check for hypertrophy (see Table 2, C7)
- narrow width (<120 msec) QRS means that the His-Purkinje system is being used
- wide width (>120 msec) QRS means that the His-Purkinje system is being bypassed or is diseased
  - BBB, VT, ventricular hypertrophy, cardiomyopathy, WPW, ectopic ventricular beat, hyperkalemia, drugs (e.g. TCAs, antiarrhythmics)
  - Q wave: the first downward deflection of the QRS complex
    - significant Q wave: ≥ 40 msec or >33% of total QRS amplitude; indicate myocardial necrosis (new or historical)
  - R and S wave abnormalities typically show pathology in terms of BBB or intraventricular abnormalities

ST SEGMENT
- one of the more famous ECG personas mostly due to its role in detecting MI
- located between QRS complex and the T wave
- corresponds to the completion of ventricular depolarization
- normally at the same level as “baseline/TP segment”
- ST elevation: at least 1 mm in 2 adjacent limb leads or at least 1-2 mm in adjacent precordial leads in STEMI (signifies occlusion and transmural ischemic injury) vs. diffuse pattern in early periocarditis
- ST depression: ischemia
  - ischemia which causes ST depression can result in myocardial damage (NSTEMI)
  - lateral wall ST depression (leads I, aVL, V5, V6) may actually indicate a STEMI in the right heart

T WAVE
- this is the repolarization phase of the ventricles (repolarization of the atria are obscured by the QRS complex)
- typically positive (except in aVR and V1) on ECG but normal isolated negative T waves may be present
- pathology when T wave variation occur in consecutive leads
  - inversion: BBB, ischemia, hypertrophy, drugs (e.g. digitalis), pulmonary embolism (lead III as part of S1Q3T3 sign)
- elevation: infarction (STEMI, Prinzmetal, hyperacute), hyperkalemia (wider, peaked)
- flattened: hypokalemia, pericarditis, drugs (e.g. digitalis), pericardial effusion
- variations: T wave alters; beat-to-beat variations due to PVC overlap (R on T phenomenon which may precipitate VT or VFib)
- appropriate T wave discordance: in BBB, T wave deflection should be opposite to that of the normal QTc is 360-450 msec for males and 360-460 for females
- corrected QT (QTc) is often used instead in practice to correct for the repolarization duration; this represents the duration of ventricular depolarization and repolarization and is often difficult to interpret
- appropriate T wave discordance suggests ischemia or infarction

Q-T INTERVAL
- this represents the duration of ventricular depolarization and repolarization and is often difficult to interpret
- corrected QT (QTc) is often used instead in place to correct for the repolarization duration: 
  \[ QTc = \frac{QT}{\sqrt{RR}} \]
- normal QTc is 360-450 msec for males and 360-460 for females
- increased (>450 msec for males and >460 for females): risk of Torsades de Pointes (a lethal tachyarrhythmia)
  - genetic Long QT Syndrome (often a channelopathy)
  - drugs: antibiotics, SSRIs, antipsychotics, antiarrhythmics
  - electrolytes: low Ca²⁺, low Mg²⁺, low K⁺
  - others: hypothyroidism, hypothermia, cardiomyopathy
- decreased (<360 msec): risk of VFib
  - electrolytes: high Ca²⁺
  - drugs: digoxin
  - others: hyperthyroidism

U WAVE
- origin unclear but may be repolarization of Purkinje fibers or delayed/prolonged repolarization of the myocardium
- more visible at slower heart rates
- deflection follows T wave with <25% of the amplitude
- variations from norm could indicate pathologic conditions:
  - prominent (>25% of T wave): electrolyte (low K⁺), drugs (digoxin, antiarrhythmics)
  - inverted (from T wave): ischemia, volume overload

Cardiac Biomarkers
- provide diagnostic and prognostic information in acute coronary syndromes and in heart failure

Ambulatory ECG
- indications for outpatient testing: palpitations, syncope, antiarrhythmic drug monitoring, arrhythmia surveillance in patients with documented or potentially abnormal rhythms, and surveillance of non-sustained arrhythmias that can lead to prophylactic intervention
- available technologies
  - Holter monitor
    - battery operated, continually records up to 3 leads for 24-48 h
    - symptoms recorded by patient on Holter clock for correlation with ECG findings
    - continuous loop recorder (diagnostic yield 66-83%)
    - worn continuously and can record data before and after patient activation for symptomatic episodes (usually worn for 2 wk)

Use of B-Type Natriuretic Peptide in the Evaluation and Management of Acute Dyspnea

Population: 452 patients (mean age 71 yr, 58% male) with acute dyspnea; patients with severe renal disease or cardiogenic shock were excluded.

Intervention: Assessment including measurement of B-type natriuretic peptide or standard assessment.

Outcome: Time to discharge and total cost of treatment.

Results: Median time to discharge was significantly shorter in the intervention group when compared with the control group (6.0 vs. 11.0 d, p=0.001).

Conclusions: In patients with acute dyspnea, measurement of B-type natriuretic peptide significantly reduced the need for admission to hospital and intensive care. The 30-d mortality rates were similar (10% vs. 12%, p=0.45).
- external and implantable devices
  - external devices can be transtelephonically downloaded
  - implantable loop recorder (ILR): cannot be transtelephonically downloaded; left in place for 14 to 18 mo

**Echocardiography**

**Transthoracic Echocardiography**
- ultrasound beams are directed across the chest wall to obtain images of the heart
- indications: evaluation of LVEF, wall motion abnormalities, myocardial ischemia and complications of MI, chamber size, wall thickness, valve morphology, proximal great vessel morphology, pericardial effusion, unexplained hypotension, murmurs, syncope, congenital heart disease
- use with Doppler to quantify degree of valvular stenosis or regurgitation

**Transoesophageal Echocardiography**
- ultrasound probe inserted into the esophagus to allow for better resolution of the heart and structures
- better visualization of posterior structures, including left atrium, mitral and aortic valves, interatrial septum
- invasive procedure used to complement transthoracic echocardiography
- indications: intracardiac thrombi, tumors, valvular vegetations (infective endocarditis), aortic dissection, aortic atheromas, prosthetic valve function, shunt, technically inadequate transthoracic study
- use with Doppler to quantify degree of valvular stenosis or regurgitation

**Stress Echocardiography**
- echocardiography in combination with either physiologic (exercise treadmill or bike testing) or pharmacologic (dobutamine infusion) stress
- validated in demonstrating myocardial ischemia and assessing viability
- provides information on the global left ventricular response to exercise
- used for valvular heart disease evaluation

**Contrast Echocardiography**
- contrast agents injected into the bloodstream to improve imaging of the heart
- conventional agent: agitated saline (contains microbubbles of air)
- allows visualization of right heart and intracardiac shunts, most commonly patent foramen ovale (PFO) and sometimes intrapulmonary shunt
- newer contrast agents are capable of crossing the pulmonary bed and achieving left heart opacification following intravenous injection; these contrast agents improve visualization of endocardial borders and enhance evaluation of LV ejection fraction, wall motion abnormalities, and intracardiac mass

**Stress Testing**

**EXERCISE TESTING**
- cardiovascular stress test that uses treadmill or bicycle exercise with electrocardiographic and blood pressure monitoring
- guidelines for use
  - patients with intermediate (10-90%) pretest probability of CAD based on age, gender, and symptoms
  - ST depression <1 mm at rest, no left bundle branch block, no digoxin or estrogen use
  - exercise test results stratify patients into risk groups
  - low risk patients can be treated medically without invasive testing
  - intermediate risk patients may need additional testing in the form of exercise imaging studies or cardiac catheterization
  - high risk patients should be referred for cardiac catheterization

**Indications for Terminating Exercise Stress Test**
- drop in systolic blood pressure of >10 mmHg from baseline despite an increase in workload, when accompanied by other evidence of ischemia
- moderate to severe angina
- ST elevation (>1 mm) in leads without diagnostic Q-waves (other than V1 or aVR)
- increasing nervous system symptoms (e.g. ataxia, dizziness, or near syncope)
- signs of poor perfusion (cyanosis or pallor)
- technical difficulties in monitoring ECG or systolic blood pressure
- patient's desire to stop
- sustained ventricular tachycardia

**Most Commonly Used Treadmill Stress Test Protocols**
- The Bruce Protocol: 7 stage test with each stage lasting 3 min. With each successive stage, the treadmill increases in both speed (2.7 km/h to 9.6 km/h) and grade (10% with a 2% increase per stage up to 22%)
- The Modified Bruce, Modified Naughton Protocol: for older individuals or those with limited exercise capacity

**Important Contraindications to Exercise Testing**
- Acute MI, aortic dissection, pericarditis, myocarditis, PE
- Severe AS, arterial HTN
- Inability to exercise adequately
Interpretation

- The most commonly used ECG criteria for a positive exercise test: ≥1 mm of horizontal or downsloping ST-segment depression or elevation (at least 60-80 msec after the end of the QRS complex).

Nuclear Cardiology

- Myocardial perfusion imaging (MPI) with ECG-gated single photon emission computed tomography (SPECT), using radiolabelled tracer.
- Evaluates myocardial viability, detects ischemia, and assesses perfusion and LV function simultaneously.
- Predicts the likelihood of further cardiac event rates independent of the patient’s history, examination, resting ECG, and stress ECG.
- Often denoted as MIBI scan with reference to radiolabelled tracer (sestamibi).
- Stress with either treadmill or IV vasodilator stress (dipyridamole [Persantine®], adenosine).
- Images of the heart obtained during stress and at rest 3-4 h later.
- Fixed defect: impaired perfusion at rest and during stress (infarcted/hibernating).
- Reversible defect: impaired perfusion only during stress (ischemic).
- Tracers:
  - Thallium-201 (201Tl, a K⁺ analogue).
  - Technetium-99 (⁹⁹Tc)-labelled tracer (sestamibi/Cardiolite® or hexamibi/Myoview®).

Stress Echocardiography

- See Stress Echocardiography, C12.

Indications for Stress Testing

- Exercise ECG:
  - Initial evaluation in patients who are able to exercise.
  - Exercise stress echo when ECG is uninterpretable.
  - Intermediate pre-test probability with normal/equivocal exercise ECG.
  - Post-ACS when used to decide on potential efficacy of revascularization.
  - To evaluate the clinical significance of valvular heart disease.

- Dobutamine stress echo (DSE):
  - Pharmacologic stress for patients who are physically unable to exercise; same indications as exercise stress echo.
  - Low dose DSE can be used to assess myocardial viability and for assessing aortic stenosis with LV systolic dysfunction.

- Exercise MPI:
  - When ECG is uninterpretable.
  - Intermediate pre-test probability with normal/equivocal exercise ECG.
  - In patients with previous imaging whose symptoms have changed.
  - To diagnose ischemia.

- Dipyridamole/Adenosine MPI:
  - To diagnose CAD in possible ACS patients with non-diagnostic ECG and negative serum biomarkers.
  - When ECG is uninterpretable due to LBBB or V-paced rhythm.
  - Among patients unable to exercise, with the same indications as exercise MPI.

Cardiac Catheterization and Angiography

- Risks of procedure related complications: vascular injury (including dissection), renal failure, stroke, MI.
- Mortality rate 0.1-0.2%.
- Invasive: catheters are introduced percutaneously into arterial and venous circulation under conscious sedation and contrast is injected.
- Arterial access most commonly through the femoral artery; radial approach gaining favor especially for obese patients and outpatients dependent on driving and ambulation.
- Venous access through the femoral vein or internal jugular vein (for patients also undergoing right heart catheterization)
- Same day procedure as outpatient.
- Indications for prehospitalization: anticoagulation, renal failure, diabetes, contrast allergy.
- Catheterization permits direct measurement of intracardiac pressures, transvalvular and mean peak pressure gradients, valve areas, cardiac output, shunt data, oxygen saturations, and visualization of coronary arteries, cardiac chambers, and great vessels.
- Angiography may provide valuable information regarding lesion severity, complexity, location, and prognosis.

Important Prognostic Factor

Duke Treadmill Score (DTS)

Weighted Index Score:

- Treadmill exercise time using standard Bruce protocol.
- Maximum net ST segment deviation (depression or elevation).
- Exercise-induced angina is diagnostic and prognostic information (such as 1 yr mortality).

\[
DTS = \text{exercise time} - (5 \times \text{MaxST}) - (4 \times \text{angina index})
\]

Angina index: 0 (no angina), 1 (angina but not exercise-limiting), 2 (exercise-limiting angina).

- DTS ≥5: 0.25% 1 yr mortality.
- DTS 4 to -10: 1.25% 1 yr mortality.
- DTS ≤-11: 5.25% 1 yr mortality.

Patients with normal imaging (nuclear perfusion or stress echo) studies at peak stress have a <1%/yr incidence of death or nonfatal MI and are thus often spared further invasive evaluation.
Right Heart Catheterization (Swan-Ganz Catheter)
- right atrial, right ventricular, and pulmonary artery pressures are recorded
- can also be used to measure the Cardiac Index (CI)
  - CI = CO/Body Surface Area
  - cardiac index is a measure of cardiac function
    - <1.8 L/min/m² usually means cardiogenic shock
    - 2.6-4.2 L/min/m² is considered normal
- pulmonary capillary wedge pressure (PCWP)
  - obtained by advancing the catheter to wedge in the distal pulmonary artery
  - records pressure measured from the pulmonary venous system
  - in the absence of pulmonary venous disease reflects left atrial pressure

Figure 17. Swan-Ganz catheter placement

Left Heart Catheterization
- systolic and end-diastolic pressure tracings recorded
- LV size, wall motion and ejection fraction can be assessed by injecting contrast into the LV (left ventriculography) via femoral/radial artery catheterization
- cardiac output (measured by the Fick oxygen method or the indicator dilution method)

Coronary Angiography
- coronary vasculature accessed via the coronary ostia
- contraindicated in severe renal failure (due to contrast agent toxicity) – must check renal status

Figure 18. Coronary angiogram schematic
AM = acute marginal; LAD = left anterior descending; OM = obtuse marginal; RCA = right coronary artery

ACC/AHA 2011 Recommended Indications for Coronary Angiography
- Disabling (CCS classes III and IV) chronic stable angina despite medical therapy
- High-risk criteria on clinical assessment or non-invasive testing
- Serious ventricular arrhythmia or CHF
- Uncertain diagnosis or prognosis after non-invasive testing
- Inability to undergo non-invasive testing

Hemodynamically significant stenosis is defined as 70% or more narrowing of the luminal diameter
Diagnostic Catheterization

- complications for diagnostic catheterization <1%
- inadequate diagnostic procedures occur in fewer than 1% of cases
- provocative pharmacological agents can be used to unmask pathology
  - fluid loading may unmask latent pericardial constriction
  - afterload reduction or inotropic stimulation may be used to increase the outflow tract gradient
  - coronary vasoreactive agents (e.g. methylergonovine, acetylcholine)
  - a variety of pulmonary vasoreactive agents in primary pulmonary HTN (e.g. oxygen, calcium channel blockers, adenosine, nitric oxide, or prostacyclin)

Contrast-Enhanced CT Coronary Angiography

- fast ECG-synchronized multi-slice CT image acquisition in the heart has enabled non-invasive imaging of the coronary arterial tree
- often used to assess coronary artery and previous graft stenosis/viability that could not be seen during coronary angiography
- sensitivity = 85%, specificity = 90% for the diagnosis of obstructive coronary disease with >50% stenosis

Magnetic Resonance Imaging

- offers high spatial resolution, eliminates the need for iodinated contrast, and does not involve exposure to ionizing radiation
- valuable in assessment of congenital cardiac anomalies, abnormalities of the aorta, and assessment of viable myocardium

CARDIAC DISEASE

Arrhythmias

Mechanisms of Arrhythmias

(I) Alterations in Impulse Formation

A. Abnormal Automaticity

- automaticity is a property of certain cardiomyocytes to spontaneously depolarize to their threshold voltage to generate action potentials in a rhythmic fashion
- under normal circumstances only cells in the specialized conduction system (SA node, AV node, and ventricular conduction system) exhibit natural automaticity. These cells are pacemaking cells. The automaticity of these cells can become abnormally increased or decreased
- in disease (e.g. post-MI ventricular ischemia) cells in the myocardium outside the conduction system may inappropriately acquire the property of automaticity and contribute to abnormal depolarization. If these ectopic generators depolarize at a rate that is greater than the SA node, they assume pacemaking control and become the source of abnormal rhythm
- automaticity can be influenced by:
  - neurohormonal tone (sympathetic and parasympathetic stimulation)
  - abnormal metabolic conditions (hypoxia, acidosis, hypothermia)
  - electrolyte abnormalities
  - drugs (e.g. digitalis)
  - local ischemia/infarction
  - other cardiac pathology
- this mechanism is responsible for the accelerated idioventricular rhythm and ventricular tachycardia that often occurs 24-72 h post MI

B. Triggered Activity due to Afterdepolarizations

1. Early Afterdepolarizations

- occur in the context of action potential prolongation
- consequence of the membrane potential becoming more positive during repolarization (e.g. not returning to baseline)
- result in self-maintaining depolarizing oscillations of action potential, generating a tachyarrhythmia (e.g. new baseline voltage is greater than threshold, which automatically triggers a new action potential after the refractory period ends)
- basis for the degeneration of QT prolongation, either congenital or acquired, into Torsades de Pointes
2. Delayed Afterdepolarizations
   - occur after the action potential has fully repolarized, but before the next usual action potential, thus called a delayed afterdepolarization
   - commonly occurs in situations of high intracellular calcium (digitalis intoxication, ischemia) or during enhanced catecholamine stimulation (e.g. “twitchy” pacemaker cells)

(II) Alterations in Impulse Conduction
A. Re-Entry Circuits
   - the presence of self-sustaining re-entry circuit causes rapid repeated depolarizations in a region of myocardium (see Figure 26, C21, for an example in the context of AV nodal re-entrant tachycardia)
     - e.g. myocardium that is infarcted/ischemic will consist of non-excitable and partially excitable zones which will promote the formation of re-entry circuits

B. Conduction Block
   - ischemia, fibrosis, trauma, and drugs can cause transient, permanent, unidirectional or bidirectional block
   - most common cause of block is due to refractory myocardium (cardiomyocytes are in refractory period or zone of myocardium unexcitable due to fibrosis)
   - if block occurs along the specialized conduction system distal zones of the conduction system can assume pacemaking control
   - conduction block can lead to bradycardia or tachycardia when impaired conduction leads to re-entry phenomenon

C. Bypass Tracts
   - normally the only conducting tract from the atria to the ventricles is the AV node into the His-Purkinje system
   - congenital/acquired accessory conducting tracts bypass the AV node and facilitate premature ventricular activation before normal AV node conduction
   - see Pre-Excitation Syndromes, C21

---

**Arrhythmias**

**Bradyarrhythmias (<60 bpm)**
- Sinus bradycardia
- Sinoatrial block
- AV block (2nd and 3rd degree)
- Junctional rhythm
- Idioventricular rhythm

**Tachyarrhythmias (>100 bpm)**
- Regular
  - Narrow QRS (SVTs)
    - Sinus tachycardia
    - Atrial tachycardia
    - Junctional tachycardia
    - AVNRT
    - AVRT (orthodromic)
    - Atrial flutter
  - Wide QRS
    - SVT with aberrancy/BBB
    - Ventricular tachycardia
    - AVRT (antichronic)
- Irregular
  - Narrow QRS (SVTs)
    - Atrial fibrillation
    - A. flutter with variable block
    - Multifocal atrial tachycardia
    - Premature atrial contraction
  - Wide QRS
    - Atrial fibrillation with BBB
    - A. flutter with BBB and variable block
    - Polymorphic VT (torsades)
    - Premature ventricular contraction

**SA NODAL DYSFUNCTION**

**Sinus Bradycardia**
- P axis normal (P waves positive in I and aVF)
- rate <60 bpm
- marked sinus bradycardia (<50 bpm) may be seen in normal adults, particularly athletes, and in elderly individuals
- caused by
  - increased vagal tone or vagal stimulation
  - vomiting
  - episodes of myocardial ischemia or infarction (inferior MI)
  - sick sinus syndrome
  - increased intracranial pressure
  - hypothyroidism
  - hypothermia
  - drugs (β-blockers, calcium channel blockers, etc.)
• treatment: if symptomatic, atropine during acute episodes; pacing for sick sinus syndrome; if drug-induced, reduction or withdrawal of drugs

Sinus Block, Pause, and Arrest
• three disorders involving the SA node in which the sinus pacemaker fires but the impulse fails to depolarize the atrial myocardium resulting in no initial P wave (and consequently no QRS complex, ST segment, or T wave)
• sinus block (SA block): a complete block or failure of the sinus node to depolarize the atria; the block can last one or more cardiac cycles and is a multiple of the normal P-P interval
• sinus pause: a delay in the formation of a sinus impulse in the SA node resulting in a temporary pause (usually >3 s)
• sinus arrest: a longer delay in the formation of a sinus impulse in the SA node
  ▪ there is no clear-cut off between sinus pause vs. arrest – if the pause lasts greater than 3x the normal P-P interval it may be called an arrest
  ▪ the P-P prolongation is not phasic or gradual (unlike sinus arrhythmia) and is not a multiple of the normal P-P interval (unlike sino-atrial block)
• escape beats or rhythm may occur:
  ▪ atrial escape: P waves with abnormal morphology
  ▪ junctional escape: P waves not seen, or follow the QRS (retrograde P), rate 40-60 bpm
  ▪ ventricular escape: no P wave; wide, abnormal QRS; slow rate 20-40 bpm

Sick Sinus Syndrome
• characterized by sinus node dysfunction (marked bradycardia, sinus pause/arrest, sinoatrial block), mainly in the elderly
  ▪ when symptomatic, electronic pacemaker is indicated
• frequently associated with episodes of atrial tachyarrhythmias ("tachy-brady syndrome")
• usually require a combination of a pacemaker for bradycardia and medications (β-blocker, calcium channel blocker, and/or digoxin, initiated after pacemaker insertion) for tachycardia

AV Conduction Blocks

First Degree AV Block
• prolonged PR interval (>200 msec)
• frequently found among otherwise healthy adults
• no treatment required

Second Degree AV Block
• some of the atrial impulses are not conducted to the ventricles
• can describe block by ratio of number of P waves to number of QRS (e.g. 2:1, 3:1, 4:1 increases in severity)
• second degree AV block is further subdivided into Type I and Type II block:
  ▪ Type I (Mobitz I) second degree AV block
    • a gradual prolongation of the PR interval precedes the failure of conduction of a P wave (Wenckebach phenomenon)
    • AV block is usually in AV node (proximal)
      – triggers (usually reversible): increased vagal tone (e.g. following surgery), RCA-mediated ischemia
      – not an indication for temporary or permanent pacing
  ▪ Type II (Mobitz II) second degree AV block
    • the PR interval is constant; there is an abrupt failure of conduction of a P wave
    • AV block is usually distal to the AV node (i.e. bundle of His)
    • increased risk of high grade or 3rd degree AV block

Figure 20. Second degree AV block with Wenckebach phenomenon (Mobitz I) (4:3 conduction) (lead V1)

Figure 21. Second degree AV block (Mobitz II) (3:2 conduction) (lead V1)
2:1 AV Block
• often not possible to determine whether the block is type I or type II
• prolonged or repeated recordings may clarify the diagnosis

Figure 22. 2:1 AV block (lead II)

Third Degree AV Block
• complete failure of conduction of the supraventricular impulses to the ventricles
• ventricular depolarization initiated by an escape pacemaker distal to the block
• QRS can be narrow or wide (junctional vs. ventricular escape rhythm)
• P-P and R-R intervals are constant, variable PR intervals
• no relationship between P waves and QRS complexes (P waves "marching through")
• management (see Electrical Pacing, C24)

Figure 23. Third degree AV block (complete heart block) (lead II)

Supraventricular Tachyarrhythmias
Presentation for SVT (and pre-excitation syndromes)
• presentation can include: palpitations, dizziness, dyspnea, chest discomfort, presyncope/syncope
• may precipitate CHF, hypotension, or ischemia in patients with underlying disease
• untreated tachycardias can cause cardiomyopathy (rare, potentially reversible with treatment of SVTs)
• includes supraventricular and ventricular rhythms

Supraventricular Tachyarrhythmias
• tachyarrhythmias that originate in the atria or AV junction
• this term is used when a more specific diagnosis of mechanism and site of origin cannot be made
• characterized by narrow QRS, unless there is pre-existing bundle branch block or aberrant ventricular conduction (abnormal conduction due to a change in cycle length)

Sinus Tachycardia
• sinus rhythm with rate >100 bpm
• occurs in normal subjects with increased sympathetic tone (exercise, emotions, pain), alcohol use, caffeinated beverages, drugs (e.g. β-adrenergic agonists, anticholinergic drugs, etc.)
• etiology: fever, hypotension, hypovolemia, anemia, thyrotoxicosis, CHF, MI, shock, PE, etc.
• treatment: treat underlying disease; consider β-blocker if symptomatic, calcium channel blocker if β-blockers contraindicated

Premature Beats
• premature atrial contraction
  ▪ ectopic supraventricular beat originating in the atria
  ▪ P wave morphology of the PAC usually differs from that of a normal sinus beat
• junctional premature beat
  ▪ ectopic supraventricular beat that originates in the vicinity of the AV node
  ▪ P wave is usually not seen or an inverted P wave is seen and may be before or closely follow the QRS complex (referred to as a retrograde, or "traveling backward" P wave)
• treatment usually not required

Atrial Flutter
• rapid, regular atrial depolarization from a macro re-entry circuit within the atrium (most commonly the right atrium)
• atrial rate 250-350 bpm, usually 300 bpm
• AV block usually occurs; it may be fixed (2:1, 3:1, 4:1, etc.) or variable
• etiology: CAD, thyrotoxicosis, mitral valve disease, cardiac surgery, COPD, PE, pericarditis
• ECG: sawtooth flutter waves (most common type of flutter) in inferior leads (II, III, aVF); narrow QRS (unless aberrancy); commonly see HR of 150

Figure 24. Atrial flutter with variable block
• in atrial flutter with 2:1 block, carotid sinus massage (first check for bruits), Valsalva maneuver, or adenosine may decrease AV conduction and bring out flutter waves
• treatment of acute atrial flutter
  • acute and if unstable (e.g. hypotension, CHF, angina): electrical cardioversion
  • if unstable (e.g. hypotension, CHF, angina): electrical cardioversion
  • if stable
    (1) rate control: β-blocker, diltiazem, verapamil, or digoxin
    (2) chemical cardioversion: sotalol, amiodarone, type I antiarrhythmics, or electrical cardioversion
  • anticoagulation guidelines same as for patients with AFib
• treatment of long-term atrial flutter: antiarrhythmics, catheter radiofrequency (RF) ablation (success rate dependent on site of origin of atrial flutter – i.e. whether right-sided isthmus-dependent or left-sided origin)

Multifocal Atrial Tachycardia
• irregular rhythm caused by presence of 3 or more atrial foci (may mimic AFib)
• atrial rate 100-200 bpm – at least 3 distinct P wave morphologies and PR intervals vary, some P waves may not be conducted
• occurs more commonly in patients with COPD, and hypoxemia; less commonly in patients with hypokalemia, hypomagnesemia, sepsis, theophylline, or digitalis toxicity
• treatment: treat the underlying cause; calcium channel blockers may be used (e.g. diltiazem, verapamil), β-blockers may be contraindicated because of severe pulmonary disease
• no role for electrical cardioversion, antiarrhythmics, or ablation

Atrial Fibrillation
• see 2014 AHA/ACC/HRS guideline for the management of patients with atrial fibrillation for details
• most common sustained arrhythmia
• incidence increases with age (10% of population >80 yr old)
• see 2014 AHA/ACC/HRS guideline for the management and care of patients with atrial fibrillation

Multifocal Atrial Tachycardia
• irregular rhythm caused by presence of 3 or more atrial foci (may mimic AFib)
• atrial rate 100-200 bpm – at least 3 distinct P wave morphologies and PR intervals vary, some P waves may not be conducted
• occurs more commonly in patients with COPD, and hypoxemia; less commonly in patients with hypokalemia, hypomagnesemia, sepsis, theophylline, or digitalis toxicity
• treatment: treat the underlying cause; calcium channel blockers may be used (e.g. diltiazem, verapamil), β-blockers may be contraindicated because of severe pulmonary disease
• no role for electrical cardioversion, antiarrhythmics, or ablation

Oral anticoagulants: “currently includes warfarin (INR 2-3) and direct oral anticoagulants (DOACs) e.g. apixaban, dabigatran, rivaroxaban

CHADS2 = 1.5; Patients either had previous thromboembolism or ≥3 risk factors.

ROCKET-AF Trial
NEJM 2011;365:883-891

Study: Prospective, non-inferiority, double blind, RCT, median follow-up of 1.9 yr.

Population: 14,264 patients with AFib (mean CHADS2 = 1.5). Patients either had previous thromboembolism or ≥3 risk factors.

Intervention: Patients were randomized to receiving rivaroxaban or warfarin.

Outcome: Composite of strokes and systemic thromboembolic event (STE).

Results: The hazard ratio of the primary outcome for rivaroxaban compared to warfarin was 0.89; 95% CI 0.74-1.03; p=0.001 for noninferiority; p=0.12 for superiority. Furthermore, the hazard ratio for major and non-major, but clinically relevant, bleeding was 1.03; 95% CI 0.96-1.11; p=0.44. There were also significant reductions in intracranial hemorrhage (0.5% vs. 0.7%, p=0.02) and fatal bleeding (0.2% vs. 0.5%, p=0.003) for rivaroxaban.

Conclusions: In patients with AFib, rivaroxaban is non-inferior to warfarin for stroke prevention and major and non-major bleeding.
A Fib on ECG
- no organized P waves due to rapid atrial activity (350-600 bpm) causing a chaotic fibrillatory baseline
- irregularly irregular ventricular response (typically 100-180 bpm), narrow QRS (unless aberrancy or previous BBB)
- wide QRS complexes due to aberrancy may occur following a long-short cycle sequence ("Ashman phenomenon")
- loss of atrial contraction, thus no “a” wave seen in JVP; no S4 on auscultation

Figure 25. Atrial fibrillation (lead II)

Management

Major objectives (RACE): all patients with AF (paroxysmal, persistent, or permanent), should be stratified using a predictive index for stroke risk and for the risk of bleeding, and most patients should receive either an oral antiocoagulant or ASA (see Table 5)
1. Rate control: β-blockers, diltiazem, verapamil (in patients with heart failure: digoxin, amiodarone)
2. Anticoagulation: use either warfarin or direct oral anticoagulant (DOACs) e.g. apixaban, dabigatran, rivaroxaban, to prevent thromboembolism
3. Cardioversion (electrical)
   - if A Fib <24-48 h, can usually cardiovert without anticoagulation if at low thromboembolic risk
   - if A Fib >24-48 h, anticoagulate for 3 wk prior and 4 wk after cardioversion due to risk of unstable intra-atrial thrombus
   - if patient unstable (hypotensive, active angina due to tachycardia, uncontrolled heart failure) should cardiovert immediately
4. Etiology
   - HTN, CAD, valvular disease, pericarditis, cardiomyopathy, myocarditis, ASD, postoperative, PE, COPD, thyrotoxicosis, sick sinus syndrome, alcohol ("holiday heart")
   - may present in young patients without demonstrable disease ("Lone A Fib") and in the elderly without underlying heart disease

Additional Management Points Regarding A Fib
- studies of patients with A Fib suggest that there is no difference in long-term survival when treating patients with a rhythm-control vs. rate-control strategy
- however, many patients with a significant underlying structural heart lesion (e.g. valve disease, cardiomyopathy) will not tolerate A Fib well (since may be dependent on atrial kick) and these patients should be cardioverted (chemical or electrical) as soon as possible

Newly Discovered A Fib
- anticoagulants may be beneficial if high risk for stroke
- if the episode is self-limited and not associated with severe symptoms, no need for antiarrhythmic drugs
- if A Fib persists, 2 options
  1. rate control and anticoagulation (as indicated above)
  2. cardioversion (as above)

Recurrent A Fib/Permanent A Fib
- if episodes are brief or minimally symptomatic, antiarrhythmic drugs may be avoided; rate control and anticoagulation are appropriate
- patients who have undergone at least one attempt to restore sinr rhythm may remain in AFib after recurrence; permanent A Fib may be accepted (with rate control and antithrombotics as indicated by CHADS2 score) in certain clinical situations
- if symptoms are bothersome or episodes are prolonged, antiarrhythmic drugs should be used
  - no or minimal heart disease: flecainide, propafenone, or sotalol
  - LV dysfunction: amiodarone
  - CAD: β-blockers, amiodarone

AV Nodal Re-Entrant Tachycardia
- re-entrant circuit using dual pathways (fast conducting β-fibers and slow conducting α-fibers) within or near the AV node; often found in the absence of structural heart disease – cause is commonly idiopathic, although familial AVNRT has been reported
- sudden onset and offset
- fast regular rhythm: rate 150-250 bpm
- usually initiated by a supraventricular or ventricular premature beat
• AVNRT accounts for 60-70% of all paroxysmal SVTs
• retrograde P waves may be seen but are usually lost in the QRS complex
• treatment
  ▪ acute: Valsalva or carotid massage, adenosine is first choice if unresponsive to vagal maneuvers; if no response, try metoprolol, digoxin, diltiazem, electrical cardioversion if patient hemodynamically unstable (hypotension, angina, or CHF)
  ▪ long-term: 1st line – β-blocker, diltiazem, digoxin; 2nd line – flecainide, propafenone; 3rd line – catheter ablation

Wolff-Parkinson-White Syndrome
• congenital defect present in 1.5-2/1,000 of the general population
• an accessory conduction tract (Bundle of Kent; can be in right or left atrium) abnormally allows early electrical activation of part of one ventricle
• impulses travel at a greater conduction velocity across the Bundle of Kent thereby effectively ‘bypassing’ AV node
• since the ventricles are activated earlier, the ECG shows early ventricular depolarization in the form of initial slurring of the QRS complex – the so-called “delta wave”
• atrial impulses that conduct to the ventricles through both the Bundle of Kent and the normal AV node/His-Purkinje system generate a broad “fusion complex”
• ECG features of WPW
  ▪ PR interval <120 msec
  ▪ delta wave: slurred upstroke of the QRS (the leads with the delta wave vary with site of bypass)
  ▪ widening of the QRS complex due to premature activation
  ▪ secondary ST segment and T wave changes
  ▪ tachyarrhythmias may occur – most often AVRT and AFib

AFib in WPW Patients
• AFib is the index arrhythmia in up to 20% of patients with WPW syndrome
  ▪ it is usually intermittent rather than persistent or permanent
• rapid atrial depolarizations in AFib are conducted through the bypass tract which is not able to filter impulses like the AV node can
• consequently the ventricular rate becomes extremely rapid (>200 bpm) and the QRS complex widens
• treatment: electrical cardioversion, IV procainamide, or IV amiodarone
  ▪ do not use drugs that slow AV node conduction (digoxin, β-blockers) as this may cause preferential conduction through the bypass tract and precipitate VF
• long-term: ablation of bypass tract if possible
AV Re-Entrant Tachycardia
- re-entrant loop via accessory pathway and normal conduction system
- initiated by a premature atrial or ventricular complex
- **orthodromic AVRT:** stimulus from a premature complex travels up the bypass tract (V to A) and down the AV node (A to V) with narrow QRS complex (no delta wave because stimulus travels through normal conduction system)
  - comprises 95% of the reentrant tachycardias associated with WPW syndrome
- **antidromic AVRT:** more rarely the stimulus goes up the AV node (V to A) and down the bypass tract (A to V); wide and abnormal QRS as ventricular activation is only via the bypass tract
- **treatment**
  - acute: similar to AVNRT except avoid long-acting AV nodal blockers, e.g. digoxin and verapamil
  - long-term: for recurrent arrhythmias ablation of the bypass tract is recommended
    * drugs such as flecaïnide and procainamide can be used

Ventricular Tachyarrhythmias

Premature Ventricular Contraction (PVC) or Ventricular Premature Beat (VPB)
- QRS width >120 msec, no preceding P wave, bizarre QRS morphology
- origin: LBBB morphology of VT = RV origin; RBBB morphology of VT = LV origin
- PVCs may be benign but are usually significant in the following situations:
  - consecutive (≥3 = VT) or multiform (varied origin)
  - PVC falling on the T wave of the previous beat (“R on T phenomenon”): may precipitate ventricular tachycardia or VF

Accelerated Idioventricular Rhythm
- ectopic ventricular rhythm with rate 50-100 bpm
- more frequently occurs in the presence of sinus bradycardia and is easily overdriven by a faster supraventricular rhythm
- frequently occurs in patients with acute MI or other types of heart disease (cardiomyopathy, hypertensive, valvular) but it does not affect prognosis and does not usually require treatment

Ventricular Tachycardia
- 3 or more consecutive ectopic ventricular complexes
  - rate >100 bpm (usually 140-200)
  - ventricular flutter: if rate >200 bpm and complexes resemble a sinusoidal pattern
  - "sustained VT" if it lasts longer than 30 s
  - ECG characteristics: wide regular QRS tachycardia (QRS usually >140 msec)
  - AV dissociation; bizarre QRS pattern
  - also favor Dx of VT: left axis or right axis deviation, nonspecific intraventricular block pattern, monophasic or biphasic QRS in V1 with RBBB, QRS concordance in V1-V6
  - occasionally during VT supraventricular impulses may be conducted to the ventricles generating QRS complexes with normal or aberrant supraventricular morphology (“ventricular capture”) or summation pattern (“fusion complexes”)
- **monomorphic VT**
  - identical complexes with uniform morphology
  - more common than polymorphic VT
  - typically result from intraventricular re-entry circuit
  - potential causes: chronic infarct scarring, acute MI/ischemia, cardiomyopathies, myocarditis, arrhythmogenic right ventricular dysplasia, idiopathic, drugs (e.g. cocaine), electrolyte disturbances
- **polymorphic VT**
  - complexes with constantly changing morphology, amplitude, and polarity
  - more frequently associated with hemodynamic instability due to faster rates (typically 200-250 bpm) vs. monomorphic VT
  - potential causes: acute MI, severe or silent ischemia, and predisposing factors for QT prolongation (see *Torsades de Pointes, C23*)
- **treatment**
  - sustained VT (>30 s) is an emergency, requiring immediate treatment
  - hemodynamic compromise: electrical cardioversion
  - no hemodynamic compromise: electrical cardioversion, lidocaine, amiodarone, type Ib agents (procainamide, quinidine)
Table 6. Wide Complex Tachycardia: Clues for Differentiating VT vs. SVT with Aberrancy*

</tr>
</tbody>
</table>

*If patient >65 yr and previous MI or structural heart disease, then chance of VT >95%

**May terminate VT in some patients with no structural heart disease

Torsades de Pointes
- a variant of polymorphic VT that occurs in patients with baseline QT prolongation – “twisting of the points”
- looks like usual VT except that QRS complexes “rotate around the baseline” changing their axis and amplitude
- ventricular rate >100 bpm, usually 150-300 bpm
- etiology: predisposition in patients with prolonged QT intervals
  - congenital long QT syndromes
  - drugs: e.g. class IA (quinidine), class III (sotalol), phenothiazines (TCAs), erythromycin, quinolones, antihistamines
  - electrolyte disturbances: hypokalemia, hypomagnesemia
  - nutritional deficiencies causing above electrolyte abnormalities
- treatment: IV magnesium, temporary pacing, isoproterenol and correct underlying cause of prolonged QT, electrical cardioversion if hemodynamic compromise

Ventricular Fibrillation (VFib)
- chaotic ventricular arrhythmia, with very rapid irregular ventricular fibrillatory waves of varying morphology
- terminal event, unless advanced cardiac life-support (ACLS) procedures are promptly initiated to maintain ventilation and cardiac output, and electrical defibrillation is carried out
- most frequent cause of sudden death
- refer to ACLS algorithm for complete therapeutic guidelines

Electrophysiology Studies
- invasive test for the investigation and treatment of cardiac rhythm disorders using intracardiac catheters
- provide detailed analysis of the arrhythmia mechanism and precise site of origin when ECG data are nondiagnostic or unobtainable
- bradyarrhythmias: define the mechanisms of SA node dysfunction and localize site of AV conduction block
- tachyarrhythmias: map for possible ablation or to assess inducibility of VT
Electrical Pacing

- the decision to implant a pacemaker usually is based on symptoms of a bradyarrhythmia or tachyarrhythmia in the setting of heart disease

Pacemaker Indications
- SA node dysfunction (most common): symptomatic bradycardia ± hemodynamic instability
- common manifestations include: syncope, presyncope, or severe fatigue
- SA node dysfunction is commonly caused by: intrinsic disease within the SA node (e.g. idiopathic degeneration, fibrosis, ischemia, or surgical trauma), abnormalities in autonomic nervous system function, and drug effects
- AV nodal-infranodal block: Mobitz II, complete heart block

Pacemaker Complications
- complications related to surgical implantation include venous access (pneumothorax, hemothorax, air embolism), pacemaker leads (perforation, malposition), pocket hematomas and infection
- complications specific to the pacemaker include a failure to pace, failure to sense, pulse generator failure, pacemaker syndrome and pacemaker mediated tachycardia

Pacing Techniques
- temporary: transvenous (jugular, subclavian, femoral) or external (transcutaneous) pacing
- permanent: transvenous into RA, apex of RV, or both
- can sense and pace atrium, ventricle, or both
- new generation: rate responsive, able to respond to physiologic demand
- biventricular

Implantable Cardioverter Defibrillators

- sudden cardiac death (SCD) usually results from ventricular fibrillation (VFib), sometimes preceded by monomorphic or polymorphic ventricular tachycardia (VT)
- ICDs detect ventricular tachyarrhythmias and are highly effective in terminating VT/VFib and in aborting SCD
- mortality benefit vs. antiarrhythmics in secondary prevention
- benefit seen in patients with ischemic and non-ischemic cardiomyopathy, depressed left ventricular ejection fraction (LVEF), prolonged QRS
- see Heart Failure, C33 for current treatment recommendations

Catheter Ablation

Techniques
- radiofrequency (RF) energy: a low-voltage high-frequency form of electrical energy (similar to cautery); RF energy produces small, homogeneous, necrotic lesions approximately 3-7 mm in diameter and 3-5 mm in depth
- cryoablation: new technology which uses a probe with a tip that can decrease in temperature to -20°C and -70°C. Produces small, necrotic lesions similar to RF ablation. When brought to -20°C, the catheter tip reversely freezes the area. Bringing the tip down to -70°C for 5 min permanently scars the tissue
  - advantage: can “test” areas before committing to an ablation
  - disadvantage: takes much longer than RF (5 min per cryoablation vs. 1 min per RF ablation)

Indications
- paroxysmal SVT
  - AVNRT: accounts for more than half of all cases
- accessory pathway (orthodromic reciprocating tachycardia): 30% of SVT
  - re-entrant rhythm, with an accessory AV connection as the retrograde limb
- corrected by targeting the accessory pathway
- atrial flutter: flutter focus in RA
- AFib: potential role for pulmonary vein ablation
- ventricular tachycardia: focus arises from the right ventricular outflow tract and less commonly originates in the inferoseptal left ventricle near the apex (note: majority of cases of VT are due to scarring from previous MI and cannot be ablated)

Major Complications
- 1% of patients
- death: 0.1-0.2%

Results:

ICDs reduced all-cause mortality by 54% (CI 37%-62%; P<0.01). The rate of ICD shocks was 5.3% (CI 4.1%-6.6%) in patients randomized to ICDs and 10.6% (CI 7.8%-13.4%) in the control group. Post-implantation complications included lead problems (1.5% CI 1.3%-1.8%); generator failure, pacemaker syndrome and pacemaker mediated tachycardia (0.3% CI 0.2%-0.4%). Rates of success of ICD implantation were 99% (CI 98.5%-99.3%) with a 16.5% (CI 15.2%-17.7%) rate of inappropriate shocks in ICD patients. Inappropriate shocks were documented in 0.3% (CI 0.2%-0.5%) of RCTs vs. 5% (CI 3.7%-7.2%) of observational studies. Rates of success of ICD implantation were 99% (CI 98.5%-99.3%) with a 16.5% (CI 15.2%-17.7%) rate of inappropriate shocks in ICD patients. Inappropriate shocks were documented in 0.3% (CI 0.2%-0.5%) of RCTs vs. 5% (CI 3.7%-7.2%) of observational studies. Rates of success of ICD implantation were 99% (CI 98.5%-99.3%) with a 16.5% (CI 15.2%-17.7%) rate of inappropriate shocks in ICD patients.
Ischemic Heart Disease

Epidemiology
- most common cause of cardiovascular morbidity and mortality
- atherosclerosis and thrombosis are the most important pathogenetic mechanisms
- M:F = 2:1 with all age groups included (Framingham study), 8:1 for age <40, 1:1 for age >70
- according to the Framingham Heart Study, men develop coronary heart disease at a rate double that of women for age <60; incidence in women triples shortly after menopause
- peak incidence of symptomatic IHD is age 50-60 (men) and 60-70 (women)
- for primary prevention of ischemic heart disease please see Family Medicine, FM7

Figure 34. Pathophysiology of atherosclerosis

Chronic Stable Angina

Definition
- symptom complex resulting from an imbalance between oxygen supply and demand in the myocardium

Etiology and Pathophysiology
- factors that decrease myocardial oxygen supply
  - decreased luminal diameter: atherosclerosis, vasospasm
  - decreased duration of diastole: tachycardia (decreased duration of diastolic coronary perfusion)
  - decreased hemoglobin: anemia
  - decreased SaO2: hypoxemia
  - congenital anomalies
• factors that increase myocardial oxygen demand  
  ▪ increased heart rate: hyperthyroidism  
  ▪ increased contractility: hyperthyroidism  
  ▪ increased wall stress: myocardial hypertrophy, aortic stenosis

Signs and Symptoms  
• typical: (1) retrosternal chest pain, tightness or discomfort radiating to left (± right) shoulder/ arm/neck/jaw, associated with diaphoresis, nausea, anxiety; (2) predictably precipitated by the "3 Es": exertion, emotion, eating; (3) brief duration, lasting <10-15 min and typically relieved by rest and nitrates  
• atypical/probable angina (meets 2 of the above); non-cardiac chest pain (meets <1 of the above)  
• Levine’s sign: clenching fist over sternum when describing chest pain  
• anginal equivalents: dysnea, acute LV failure, flash pulmonary edema

Clinical Assessment  
• history including directed risk factor assessment and physical exam  
• labs: Hb, fasting glucose, fasting lipid profile  
• ECG (at rest and during episode of chest pain if possible)  
• CXR (suspected heart failure, valvular disease, pericardial disease, aortic dissection/aneurysm, or signs or symptoms of pulmonary disease)  
• stress testing (see Cardiac Diagnostic Tests, C5) or angiography  
  ▪ echo  
  ▪ to assess systolic murmur suggestive of aortic stenosis, mitral regurgitation, and/or HCM  
  ▪ to assess LV function in patients with Hx of prior MI, pathological Q waves, signs or symptoms of CHF

Differential Diagnosis  
• see Differential Diagnoses of Common Presentations, CA

Treatment of Chronic Stable Angina

1. General measures  
  ▪ goals: to reduce myocardial oxygen demand and/or increase oxygen supply  
  ▪ lifestyle modification (diet, exercise)  
  ▪ treatment of risk factors: statins (see Endocrinology, E5, Family Medicine, FM9 for target lipid guidelines), antihypertensives, etc.  
  ▪ pharmacological therapy to stabilize the coronary plaque to prevent rupture and thrombosis

2. Antiplatelet therapy (first-line therapy)  
  ▪ ASA  
  ▪ clopidogrel when ASA absolutely contraindicated

3. β-blockers (first-line therapy – improve survival in patients with HTN)  
  ▪ increase coronary perfusion and decrease demand (HR, contractility) and BP (afterload)  
  ▪ cardioselective agents preferred (e.g. metoprolol, atenolol) to avoid peripheral effects (inhibition of vasodilation and bronchodilation via β2 receptors)  
  ▪ avoid intrinsic sympathomimetics (e.g. acebutolol) which increase demand

4. Nitrates (symptomatic control, no clear impact on survival)  
  ▪ decrease preload (venous dilatation) and afterload (arteriolar dilatation), and increase coronary perfusion  
  ▪ maintain daily nitrate-free intervals to prevent tolerance (tachyphylaxis)

5. Calcium channel blockers (CCBs, second-line or combination)  
  ▪ increase coronary perfusion and decrease demand (HR, contractility) and BP (afterload)  
  ▪ caution: verapamil/diltiazem combined with β-blockers may cause symptomatic sinus bradycardia or AV block

6. ACE inhibitors (ACEI, not used to treat symptomatic angina)  
  ▪ angina patients tend to have risk factors for CV disease which warrant use of an ACEI (e.g. HTN, DM, proteinuric renal disease, previous MI with LV dysfunction)  
  ▪ benefit in all patients at high risk for CV disease (concomitant DM, renal dysfunction, or LV systolic dysfunction)  
  ▪ angiotensin II receptor blockers (ARBs) can be used when ACEI contraindicated (e.g. hypersensitivity, angioedema)

7. Invasive strategies  
  ▪ revascularization (see Coronary Revascularization, C31 and COURAGE trial sidebar)

VARIANT ANGINA (Prinzmetal’s Angina)  
• myocardial ischemia secondary to coronary artery vasospasm, with or without atherosclerosis  
• uncommonly associated with infarction or LV dysfunction  
• typically occurs between midnight and 8 AM, unrelated to exercise, relieved by nitrates  
• typically ST elevation on ECG  
• diagnosed by provocative testing with ergot vasoconstrictors (rarely done)  
• treat with nitrates and CCBs

SYNDROME X  
• typical symptoms of angina but normal angiogram  
• may show definite signs of ischemia with exercise testing  
• thought to be due to inadequate vasodilator reserve of coronary resistance vessels  
• better prognosis than overt epicardial atherosclerosis

Canadian Cardiovascular Society (CCS) Functional Classification of Angina  
• Class I: ordinary physical activity (walking, climbing stairs) does not cause angina; angina with strenuous, rapid, or prolonged activity  
• Class II: slight limitation of ordinary activity; angina brought on at >2 blocks on level or climbing >1 flight of stairs or by emotional stress  
• Class III: marked limitation of ordinary activity: angina brought on at <2 blocks on level or climbing <1 flight of stairs  
• Class IV: inability to carry out any physical activity without discomfort; angina may be present at rest

Optimal Medical Therapy With or Without PCI for Stable Coronary Disease. COURAGE Trial NEJM 2007;356:1503-1516  
Study: Randomized, controlled trial with median follow-up of 4.6 yr.  
Population: 2,287 patients who had objective evidence of myocardial ischemia and significant stable coronary artery disease.  
Intervention: Patients were randomized to receive intensive pharmacologic therapy and lifestyle intervention with or without percutaneous coronary intervention (PCI).  
Outcome: Primary outcome was all-cause mortality and nonfatal myocardial infarction (MI). Secondary outcome had additional events of stroke, all MI, and hospitalization for unstable angina with negative biomarkers.  
Results: There was no significant difference in primary (unadjusted hazard ratio: 1.05, p=0.62) or secondary outcomes (hazard ratio: 1.05, p=0.62) between the PCI and non-PCI intervention groups. The PCI group had significantly lower rates of subsequent revascularization at 4.6 yr of follow-up (hazard ratio 0.60, p<0.001) and was more angina-free in the first 4 yr of follow-up.  
Conclusions: PCI as an adjunct in initial management in patients with significant stable coronary artery disease does not reduce mortality, MI, stroke, or hospitalization for ACS, but does provide angina relief and reduced risk of revascularization.
Acute Coronary Syndromes

Definition
- ACS includes the spectrum of UA, NSTEMI, and STEMI; this distinction aids in providing the appropriate therapeutic intervention
- MI is defined by evidence of myocardial necrosis. It is diagnosed by a rise/fall of serum markers plus any one of:
  - symptoms of ischemia (chest/upper extremity/mandibular/epigastric discomfort; dyspnea)
  - ECG changes (ST-T changes, new BBB or pathological Q waves)
  - imaging evidence (myocardial loss of viability, wall motion abnormality, or intracoronary thrombus)
- if biomarker changes are unattainable, cardiac symptoms combined with new ECG changes is sufficient
- NSTEMI meets criteria for myocardial infarction without ST elevation or BBB
- STEMI meets criteria for myocardial infarction characterized by ST elevation or new BBB
- UA is clinically defined by any of the following:
  - accelerating pattern of pain: increased frequency, increased duration, decreased threshold of exertion, decreased response to treatment
  - angina at rest
  - new-onset angina
  - angina post-MI or post-procedure (e.g. percutaneous coronary intervention [PCI], coronary artery bypass grafting [CABG])

Investigations
- history and physical
  - note that up to 30% of MIs are unrecognized or “silent” due to atypical symptoms – more common in women, DM, elderly, post-heart transplant (because of denervation)
- ECG
- CXR
- labs
  - serum cardiac biomarkers for myocardial damage (repeat 8 h later) (see Cardiac Biomarkers, C11)
  - CBC, INR/PTT, electrolytes and magnesium, creatinine, urea, glucose, serum lipids
  - draw serum lipids within 24-48 h because values are unreliable from 2-48 d post-MI

MANAGEMENT OF ACUTE CORONARY SYNDROMES

1. General measures
   - ABCs: assess and correct hemodynamic status first
   - bed rest, cardiac monitoring, oxygen
   - nitroglycerin SL followed by IV
   - morphine IV

2. Anti-platelet and anticoagulation therapy
   - ASA (81mg) chewed
   - NSTEMI
     - ticagrelor in addition to ASA or if ASA contraindicated, subcutaneous low molecular weight heparin or IV unfractionated heparin (UFH) (LMWH preferable, except in renal failure or if CABG is planned within 24 h)
     - clopidogrel used if patient ineligible for ticagrelor and prasugrel
     - prasugrel contraindicated in those with a history of stroke/TIA, and avoidance of or lower dose is recommended for those >75 yr old or weighing <60 kg (TRITON-TIMI 38)
   - anticoagulation options depend on reperfusion strategy
     - primary PCI: UFH during procedure; bivalirudin is a possible alternative
     - thrombolysis: LMWH (enoxaparin) until discharge from hospital; can use UFH as alternative because of possible rescue PCI
     - no reperfusion: LMWH (enoxaparin) until discharge from hospital
     - continue LMWH or UFH followed by oral anticoagulation at discharge if at high risk for thromboembolic event (large anterior MI, AFib, severe LV dysfunction, CHF, previous DVT or PE, or echo evidence of mural thrombus)

3. β-blockers
   - first dose IV followed by oral administration
   - STEMI: contraindications include signs of heart failure, low output states, risk of cardiogenic shock, heart block, asthma or airway disease; initiate orally within 24 h of diagnosis when indicated
if β-blockers are contraindicated or if β-blockers/nitrates fail to relieve ischemia, non-dihydropyridine calcium channel blockers (e.g. diltiazem, verapamil) may be used as second-line therapy in the absence of severe LV dysfunction or pulmonary vascular congestion (calcium channel blockers do not prevent MI or decrease mortality)

4. Invasive strategies and reperfusion options

- UA/NSTEMI: early coronary angiography ± revascularization if possible is recommended with any of the following high-risk indicators:
  - recurrent angina/ischemia at rest despite intensive anti-ischemic therapy
  - CHF or LV dysfunction
  - hemodynamic instability
  - high (≥3) TIMI risk score (tool used to estimate mortality following an ACS)
  - sustained ventricular tachycardia
  - dynamic ECG changes
  - high-risk findings on non-invasive stress testing
  - PCI within the previous 6 mo
  - repeated presentations for ACS despite treatment and without evidence of ongoing ischemia or high risk features
  - note: thrombolyis is NOT administered for UA/NSTEMI

- STEMI
  - after diagnosis of STEMI is made, do not wait for results of further investigations before implementing reperfusion therapy
  - goal is to re-perfuse artery: thrombolysis ("EMS-to-needle") within 30 min or primary PCI ("EMS-to-balloon") within 90 min (depending on capabilities of hospital and access with PCI facility)
  - thrombolysis
    - preferred if patient presents ≤12 h of symptom onset, and <30 min after presentation to hospital, has contraindications to PCI, or PCI cannot be administered within 90 min
  - PCI
    - early PCI (≤12 h after symptom onset and <90 min after presentation) improves mortality vs. thrombolysis with fewer intra-cranial hemorrhages and recurrent MIs
    - rescue PCI: following failed thrombolytic therapy (diagnosed when following thrombolysis, ST segment elevation fails to resolve below half its initial magnitude and patient still having chest pain)

Figure 35. Reperfusion strategy in STEMI

Enoxaparin vs. Unfractionated Heparin with Fibrinolysis for ST-Elevation Myocardial Infarction

Study: Prospective multicenter RCT.

Patients: 20,479 patients (median age 60 yr. 77% male) with STEMI who were scheduled to undergo thrombolysis.

Intervention: Patients were randomized to receive either enoxaparin or weight based unfractionated heparin in addition to thrombolysis and standard therapies.

Primary Outcome: Death or recurrent nonfatal MI 30 d post-event.

Results: The composite primary outcome occurred less often in the enoxaparin group compared with those who received unfractionated heparin (9.9% vs. 12.0%, p = 0.001, NNT = 47). Taken separately, there was a trend toward reduced mortality (6.9% vs. 7.5%, p = 0.11) and a significant reduction in nonfatal reinfarction (3.0% vs. 4.5%, p < 0.001) in the enoxaparin group. The risk of major bleeding was significantly increased in the enoxaparin group (2.1% vs. 1.4%, p < 0.001, NNH = 142).

Conclusion: In patients with STEMI receiving thrombolysis, enoxaparin is superior to unfractionated heparin in preventing recurrent nonfatal MI and may lead to a small reduction in mortality.
Long-Term Management of ACS

- risk of progression to MI or recurrence of MI or death is highest within 1 mo
- at 1-3 mo after the acute phase, most patients resume a clinical course similar to that in patients with chronic stable coronary disease
- pre-discharge workup: ECG and echo to assess residual LV systolic function
- drugs required in hospital to control ischemia should be continued after discharge in all patients
- other medications for long-term management of ACS are summarized below

1. General Measures
   - education
   - risk factor modification

2. Antiplatelet and Anticoagulation Therapy
   - EÇASA 81 mg daily
   - ticagrelor 90 mg twice daily or prasugrel 10 mg daily (at least 1 mo, up to 9-12 mo, if stent placed at least 12 mo)
   - clopidogrel 75 mg daily can be used as alternatives to ticagrelor and prasugrel when indicated
   - ± warfarin x 3 mo if high risk (large anterior MI, LV thrombus, LVEF <30%, history of VTE, chronic AFib)

3. β-Blockers (e.g. metoprolol 25-50 mg bid or atenolol 50-100 mg daily)

4. Nitrates
   - alleviate ischemia but do not improve outcome
   - use with caution in right-sided MI patients who have become preload dependent

5. Calcium Channel Blockers (NOT recommended as first line treatment, consider as alternative to β-blockers)

6. Angiotensin-Converting Enzyme Inhibitors
   - prevent adverse ventricular remodelling
   - recommended for asymptomatic high-risk patients (e.g. diabetics), even if LVEF >40%
   - recommended for symptomatic CHF, reduced LVEF (<40%), anterior MI
   - use ARBs in patients who are intolerant of ACEI

7. ± Aldosterone Antagonists
   - if on ACEI and β-blockers and LVEF <40% and CHF or DM
   - significant mortality benefit shown with eplerenone by 30 d

8. Statins (early, intensive, irrespective of cholesterol level; e.g. atorvastatin 80 mg daily)

9. Invasive Cardiac Catheterization if indicated (risk stratification)

Post-Infarction Risk Stratification

High Risk (30-35%)
- Prior MI
- CHF
- Recurrent Ischemia
- High-Risk Arrhythmia

Intermediate/Low-Risk (65-70%)

Non-Invasive Stress Testing

Ischemia or Poor Functional Status

Cardiac Catheterization

*note: echo done routinely post-MI

Figure 36. Post-MI risk stratification

Prognosis following STEMI

- 5-15% of hospitalized patients will die
- risk factors
  - infarct size/severity
  - age
  - comorbid conditions
  - development of heart failure or hypotension
- post-discharge mortality rates
  - 6-8% within first year, half of these within first 3 mo
  - 4% per year following first yr
- risk factors
  - LV dysfunction
  - residual myocardial ischemia
  - ventricular arrhythmias
  - history of prior MI

Intensive vs. Moderate Lipid Lowering with Statins after Acute Coronary Syndromes

**Study:** Prospective, double blind, RCT; mean follow-up of 2 yr.
**Population:** 4,162 patients who had been hospitalized for an ACS within the preceding 10 d.
**Intervention:** Patients were randomized to receiving pravastatin 40 mg or atorvastatin 80 mg daily.
**Primary Outcome:** Composite of death from any cause, myocardial infarction, documented unstable angina requiring rehospitalization, revascularization (performed at least 30 d after randomization), and stroke.
**Results:** High dose atorvastatin was associated with a 16% hazard ratio reduction (p=0.005; 95% CI 5-26%) in the primary outcome compared to standard dose pravastatin.
**Conclusions:** In patients who recently experienced an ACS, high dose statin therapy provides greater protection against death and major cardiovascular events than standard dose therapy.

Long-term anti-anginal therapy

ECG = electrocardiogram; LMWH = low-molecular-weight heparin; NSTEMI = non-ST-segment elevation myocardial infarction;
PCI = percutaneous coronary intervention; STEMI = ST-segment elevation myocardial infarction

Elevated troponin

Figure 37. Treatment algorithm for patients with symptoms suggestive of an acute coronary syndrome

**Sudden Cardiac Arrest**

**Definition**
- unanticipated, non-traumatic cardiac death in a stable patient which occurs within 1 h of symptom onset; VFib is most common cause

**Etiology**
- primary cardiac pathology
  - ischemia/MI
  - LV dysfunction
  - severe ventricular hypertrophy
    - HCM
    - AS
  - long QT syndrome
  - congenital heart disease
  - mutations in cardiac ion channels

**Management**
- acute: resuscitate with prompt CPR and defibrillation
- investigate underlying cause (cardiac catheterization, electrophysiologic studies, echo)
- treat underlying cause
- antiarrhythmic drug therapy: amiodarone, β-blockers
- implantable cardioverter defibrillator (ICD)
- refer to ACLS guidelines (see Anesthesia, A32)

**Coronary Revascularization**

**PERCUTANEOUS CORONARY INTERVENTION**
- interventional cardiology technique aimed at relieving significant coronary stenosis
- main techniques: balloon angioplasty, stenting
- less common techniques: rotational/directional/extraction atherectomy

**Balloon Angioplasty and Intracoronary Stenting**
- coronary lesions dilated with balloon inflation
- major complication is restenosis (approximately 15% at 6 mo), felt to be due to elastic recoil and neointimal hyperplasia
- majority of patients receive intracoronary stent(s) to prevent restenosis
  - bare metal stent (BMS)
  - drug-eluting stent (DES)
    - coated with antiproliferative drugs (sirolimus, paclitaxel)
    - reduced rate of neointimal hyperplasia and restenosis compared to BMS (5% vs. 20%)
    - complication: late stent thrombosis (5 events per 1,000 stents implanted)

**Adjunctive Therapies**
- ASA and heparin decrease post-procedural complications
- further reduction in ischemic complications has been demonstrated using GPIIb/IIIa inhibitors (abciximab, epifibatide, tirofiban) in coronary angiography and stenting
- following stent implantation
  - dual antiplatelet therapy (ASA and clopidogrel) for 1 mo with BMS or ≥12 mo with DES
  - ASA and prasugrel can be considered for those at increased risk of stent thrombosis

**Procedural Complications**
- mortality and emergency bypass rates <1%
- nonfatal MI: approximately 2-3%

**CORONARY ARTERY BYPASS GRAFT SURGERY**
- objective of CABG is complete reperfusion of the myocardium

**Indications**
- CABG
  - ≥50% diameter stenosis in the left main coronary artery
  - ≥70% diameter stenosis in three major coronary arteries
  - ≥70% diameter stenosis in the proximal LAD artery plus one other major coronary artery
- Survivors of sudden cardiac arrest with presumed ischemia-mediated VT caused by significant (≥70% diameter) stenosis in a major coronary artery
- Other
  - ≥70% diameter stenosis in two major coronary arteries (without proximal LAD disease) and evidence of extensive ischemia
  - ≥70% diameter stenosis in the proximal LAD artery and evidence of extensive ischemia
  - Multivessel CAD in patients with diabetes
  - LV systolic dysfunction (LVEF 35-50%) and significant multivessel CAD or proximal LAD stenosis where viable myocardium is present in the region of intended revascularization
- PCI
  - UA/NSTEMI if not a CABG candidate
  - STEMI when PCI can be performed more rapidly and safely than CABG
- CABG or PCI
  - One or more significant (≥70% diameter) coronary artery stenosis amenable to revascularization and unacceptable angina despite medical therapy

<tr>
<td>Right Gastroepiploic Artery</td>
<td>80-90% patency at 5 yr</td>
<td>Primarily used as an in situ graft to bypass the RCA</td>
</tr>
</tbody>
</table>

### Operative Issues
- Left ventricular (LV) function is an important determinant of outcome of all heart diseases
- Patients with severe LV dysfunction usually have poor prognosis, but surgery can sometimes dramatically improve LV function
- Assess viability of non-functioning myocardial segments in patients with significant LV dysfunction using delayed thallium myocardial imaging, PET scanning, or MRI

### CABG and Antiplatelet Regimens
- Please refer to 2011 ACCF/AHA Guideline for Coronary Artery Bypass Graft Surgery for more information
- Prior to CABG, clopidogrel and ticagrelor should be discontinued for 5 d and prasugrel for 7 d before surgery
- Dual antiplatelet therapy should be continued for 12 mo in patients with ACS within 48-72 h after CABG
- ASA (81mg) continued indefinitely (can be started 6 h after surgery)
- Patients requiring CABG after PCI should continue their dual antiplatelet therapy as recommended in the post-PCI guidelines
heart failure: a complex clinical syndrome, resulting from almost any cardiac disorder that impairs the ability of the ventricle to fill with or eject blood
• backward heart failure: heart unable to accommodate venous return resulting in elevated filling pressures and vascular congestion (systemic or pulmonary)
• heart failure can involve left side of heart (left heart failure), right side (right heart failure), or both (biventricular failure) (see Table 13)
• heart failure can also have components of ineffective ventricular filling (diastolic dysfunction) and/or contraction (systolic dysfunction)
• most cases associated with poor cardiac output (low-output heart failure); however, some cases of CHF not due to intrinsic cardiac disease but instead due to increased demand (high-output heart failure)

Procedural Complications
• CABG using cardiopulmonary bypass (CPB)
  • stroke and neurocognitive defects (microembolization of gaseous and particulate matter)
  • immunosuppression
  • systemic inflammatory response leading to:
    • myocardial dysfunction
    • renal dysfunction
    • neurological injury
    • respiratory dysfunction
  • coagulopathies

OFF-PUMP CORONARY ARTERY BYPASS SURGERY

Procedure
• avoids the use of CPB by allowing surgeons to operate on a beating heart
  • stabilization devices (e.g. Genzyme Immobilizer®) hold heart in place allowing operation while positioning devices (Medtronic Octopus® and Starfish® system) allow the surgeon to lift the beating heart to access the lateral and posterior vessels
• procedure is safe and well tolerated by most patients; however, this surgery remains technically more demanding

Indications
• used in poor candidates for CPB who have: calcified aorta, poor LVEF, severe peripheral vascular disease (PVD), severe COPD, chronic renal failure, coagulopathy, transfusion objections (e.g. Jehovah’s Witness), good target vessels, anterior/lateral wall revascularization, target revascularization in older, sicker patients
• absolute contraindications: hemodynamic instability, poor quality target vessels including intramycocardial vessels, diffusely diseased vessels, and calcified coronary vessels
• relative contraindications: cardiomegaly/CHF, critical left main disease, small distal targets, recent or current acute MI, cardiogenic shock, LVEF <35%

Outcomes
• OPCAB decreases in-hospital morbidity (decreased incidence of chest infection, inotropic requirement, supraventricular arrhythmia), blood product transfusion, ICU stay, length of hospitalization, and CK-MB and troponin I levels
• no significant difference in terms of survival at 2 yr, frequency of cardiac events (MI, PCI, CHF, recurrent angina, redo CABG), or medication usage compared to on-pump CABG
Pathophysiology

- primary insults (myocyte loss, overload) → pump dysfunction, which leads to:
  - remodeling (dilatation, hypertrophy)
  - neurohumoral activation → necrosis and apoptosis
- both pathways result in further damage (re-starting the cycle), edema, tachycardia, pump dysfunction, which leads to:
  - primary insults (myocyte loss, overload)
- systemic response to ineffective circulating volume

Systolic Dysfunction

- impaired myocardial contractile function → decreased LVEF and SV → decreased CO
- findings: apex beat displaced, S3, increased heart size on CXR, decreased LVEF, LV dilatation
- causes
  - ischemic (e.g. extensive CAD, previous MI)
  - non-ischemic
    - HTN
    - DM
    - alcohol (and other toxins)
    - myocarditis
    - dilated cardiomyopathy (multiple causes – see Dilated Cardiomyopathy, C39)

Heart Failure with Preserved Ejection Fraction

- previously known as ‘diastolic dysfunction’
- up to 1/2 of all HF patients have normal systolic function (i.e. normal ejection fraction) and the cause of heart failure is impaired diastolic filling: prevalence higher in older patients
- increased LV filling pressures produce venous congestion upstream (i.e. pulmonary and systemic venous congestion)
- findings: HTN, apex beat sustained, S4, normal-sized heart on CXR, LVH on ECG/echo, normal LVEF
- causes of decreased compliance:
  - transient: ischemia (relaxation of myocardium is active and requires ATP)
  - permanent
    - severe hypertrophy (HTN, aortic stenosis, HCM)
    - restrictive cardiomyopathy (e.g. amyloid)
    - MI

High-Output Heart Failure

- caused by demand for increased cardiac output
- often exacerbates existing heart failure or decompensates a patient with other cardiac pathology
- differential diagnosis: anemia, thiamine deficiency (beriberi), hyperthyroidism, A-V fistula or L-R shunting, Paget’s disease, renal disease, hepatic disease
Etiologies of Primary Insults
- consider predisposing, precipitating, and perpetuating factors

Precipitants of Symptomatic Exacerbations
- consider natural progression of disease vs. new precipitant
- always search for reversible cause
- differential diagnosis can also be organized as follows:
  - new cardiac insult/disease: MI, arrhythmia, valvular disease
  - new demand on CV system: HTN, anemia, thyrotoxicosis, infection, etc.
  - failure to take medications as prescribed

Investigations
- identify and assess precipitating factors and treatable causes of CHF
- blood work: CBC, electrolytes (including calcium and magnesium), BUN, creatinine, fasting blood glucose, HbA1c, lipid profile, liver function tests, serum TSH, ± ferritin, BNP, uric acid
- ECG: look for chamber enlargement, arrhythmia, ischemia/infarction
- CXR: cardiomegaly, pleural effusion, redistribution, Kerley B lines, bronchiolar-alveolar cuffing
- echo: LVEF, cardiac dimensions, wall motion abnormalities, valvular disease, pericardial effusion
- radionuclide angiography: LVEF
- myocardial perfusion scintigraphy (thallium or sestamibi SPECT)

Acute Treatment of Pulmonary Edema
- treat acute precipitating factors (e.g. ischemia, arrhythmias)
- L = Lasix® (furosemide) 40-500 mg IV
- M = morphine 2-4 mg IV: decreases anxiety and preload (venodilation)
- N = nitroglycerin: topical/IV/SL
- O = oxygen: in hypoxemic patients
- P = positive airway pressure (CPAP/BiPAP): decreases preload and need for ventilation when appropriate
- P = position: sit patient up with legs hanging down unless patient is hypotensive
- in ICU setting or failure of LMNOPP, other interventions may be necessary
  - dopamine
    - low dose: selective renal vasodilation (high potency D1 agonist)
    - medium dose: inotropic support (medium potency β1 agonist)
    - high dose: increases SVR (low potency β1 agonist), which is undesirable
  - dobutamine
    - selective inotropic (β1 agonist) and arterial vasodilator (β1 antagonist)
  - phosphodiesterase inhibitors (milrinone)
    - inotropic effect and vascular smooth muscle relaxation (decreased SVR), similar to dobutamine
  - consider pulmonary artery catheter to monitor pulmonary capillary wedge pressure (PCWP)
  - if patient is unstable or a cardiac etiology is uncertain (PCWP >18 indicates likely cardiac failure)
  - mechanical ventilation as needed
  - rarely used, but potentially life-saving measures:
    - intra-aortic balloon pump (IABP)
    - left or right ventricular assist device (LVAD/RVAD)
    - cardiac transplant

Long-Term Management
- note that most evidence-based management applies to HFPEF
- priorities in HFPEF focus on controlling systolic and diastolic HTN, as a risk factor control measure

Conservative Measures
- symptomatic measures: oxygen in hospital, bedrest, elevate the head of bed
- lifestyle measures: diet, exercise, DM control, smoking cessation, decrease alcohol consumption, patient education, sodium and fluid restriction
- multidisciplinary heart failure clinics: for management of individuals at higher risk, or with recent hospitalization
Non-Pharmacological Management
• cardiac rehabilitation: participation in a structured exercise program for NYHA class I-III after clinical status assessment to improve quality of life (HF-ACTION trial)

Pharmacological Therapy

1. Vasodilators
   • ACEI: standard of care – slows progression of LV dysfunction and improves survival
     • all symptomatic patients functional class II-IV
     • all asymptomatic patients with LVEF <40%
     • post-MI
     • angiotensin II receptor blockers
       • second-line to ACEI if not tolerated, or as adjunct to ACEI if β-blockers not tolerated
       – hydralazine and nitrates
     • second-line to ACEI, decrease in mortality not as great as with ACEI
     • may consider in acute renal failure until creatinine stabilizes

2. β-blockers: slow progression and improve survival
   • class I-III with LVEF <40%
   • stable class IV patients
   • note: should be used cautiously, titrate slowly because may initially worsen CHF

3. Diuretics: symptom control, management of fluid overload
   • furosemide (40-500 mg daily) for potent diuresis
   • metolazone may be used with furosemide to increase diuresis
   • furosemide, metolazone, and thiazides oppose the hyperkalemia that can be induced by β-blockers, ACEI, ARBs, and aldosterone antagonists

4. Mineralocorticoid receptor (aldosterone) antagonists: mortality benefit in symptomatic heart failure and severely depressed ejection fraction
   • spironolactone for class IIIb and IV CHF already on ACEI and loop diuretic
   • eplerenone may be considered if intolerable endocrine side effects
   • note: potential for life threatening hyperkalemia
     • monitor K+ after initiation and avoid if Cr >2.9 mg/dL or K+ >5.2 mEq/L

5. Digoxin and cardiac glycosides: digoxin improves symptoms and decreases hospitalizations, no effect on mortality
   • indications: patient in sinus rhythm and symptomatic on ACEI, or CHF and AFib
   • patients on digitals glycosides may worsen if these are withdrawn

6. Antiarrhythmic drugs: for use in CHF with arrhythmia
   • can use amiodarone, β-blocker, or digoxin

7. Anticoagulants: warfarin for prevention of thromboemolic events
   • prior thromboembolic event or AFib, presence of LV thrombus on echo
   • possible benefit in other patients with LVEF <30% (controversial)

Procedural Interventions
• resynchronization therapy: symptomatic improvement with biventricular pacemaker
  • consider if QRS >130 msec, LVEF <35%, and severe symptoms despite optimal therapy
  • greatest benefit likely with marked LV enlargement, mitral regurgitation, QRS >150 msec, high diuretic requirement
• ICD: mortality benefit in 1st prevention of sudden cardiac death
  • prior MI, optimal medical therapy, LVEF <30%, clinically stable
  • prior MI, non-sustained VT, LVEF 30-40%, EPS inducible VT
• LVAD/RVAD (see Ventricular Assist Devices, C38)
• cardiac transplantation (see Cardiac Transplantation, C37)
• valve repair if patient is surgical candidate and has significant valve disease contributing to CHF (see Valvular Heart Disease, C41)
Sleep-Disordered Breathing

- 45-55% of patients with CHF have sleep disturbances, including Cheyne-Stokes breathing and sleep apnea (central or obstructive)
- associated with a worse prognosis and greater LV dysfunction
- nasal continuous positive airway pressure (CPAP) is effective in treating symptoms of sleep apnea with secondary beneficial effects in cardiac function and symptoms

Cardiac Transplantation

- treatment for end-stage heart disease; due to ischemic or non-ischemic cardiomyopathy
- worldwide 1 yr survival is 85-90%, 5 yr survival about 60%, annual mortality rate of 4%
- matching is according to blood type, body size and weight (should be within 25%), and HLA tissue matching (if time allows)

Indications for Surgery

- severe cardiac disability despite maximal medical therapy (recurrent hospitalizations for CHF, NYHA III or IV, peak metabolic oxygen consumption <14 mL/kg/min in absence of β-blocker)
- symptomatic cardiac ischemia refractory to conventional treatment (unstable angina not amenable to CABG or PCI with LVEF <30%; recurrent, symptomatic ventricular arrhythmias)
- exclusion of all surgical alternatives to cardiac transplantation

Prerequisites

- emotionally stable with social support
- medically compliant and motivated
- relative contraindications: incurable malignancy, major systemic illness, irreversible major organ disease, active systemic infection (e.g. hepatitis C, HIV), obesity, irreversible pulmonary HTN (pulmonary vascular resistance [PVR] >6 Wood units), severe COPD (FEV₁ <1 L) or active drug addiction or alcoholism

Complications

- rejection
  - common, <5% have serious hemodynamic compromise
  - gold standard to detect rejection: endomyocardial biopsy
  - no noninvasive tests to detect rejection
  - risk of acute rejection is greatest during the first 3 mo after transplant
- infection
  - leading cause of morbidity and mortality after cardiac transplantation
  - risk peaks early during the first few months after transplantation and then declines to a low persistent rate
- allograft CAD
  - approximately 50% develop graft CAD within 5 yr of transplantation
  - most common cause of late death following transplantation
- malignancy
  - develops in 15% of cardiac transplant recipients due to immunosuppressive medication
second most common cause of late death following transplantation
• cutaneous neoplasms most common, followed by non-Hodgkin's lymphoma and lung cancer
• immunosuppressive medication side effects (prednisone, cyclosporine, tacrolimus, sirolimus)

**Ventricular Assist Devices**

• work to unload the ventricle while maintaining output; also results in decreased myocardial oxygen consumption permitting recovery of the myocardium that is not irreversibly injured
• can support the left (LVAD), right (RVAD), or both ventricles (BiVAD)
• indications
  • bridge to transplantation
  • post-operative mechanical support when unable to separate from cardiopulmonary bypass despite inotropic and intra-aortic balloon pump (IABP) support
    • IABP is a catheter based device inserted into the aorta via the femoral artery that decreases myocardial O₂ demand and increases blood flow to coronary arteries
  • post-operative cardiogenic shock

**Myocardial Disease**

**Definition of Cardiomyopathy**

• intrinsic or primary myocardial disease not secondary to congenital, hypertensive, coronary, valvular, or pericardial disease
• functional classification: dilated, hypertrophic, or restrictive
• LV dysfunction 2º to MI often termed “ischemic cardiomyopathy”, is not a true cardiomyopathy (i.e. primary myocardial disorder) since the primary pathology is obstructive CAD

**Myocarditis**

**Definition**

• inflammatory process involving the myocardium ranging from acute to chronic; an important cause of dilated cardiomyopathy

**Etiology**

• idiopathic
• infectious
  • viral (most common): parvovirus B19, influenza, coxsackie B, echovirus, poliovirus, HIV, mumps
  • bacterial: *S. aureus, C. perfringens, C. diphtheriae, Mycoplasma, Rickettsia*
  • fungi
  • spirochetal (Lyme disease – *Borrelia burgdorferi*)
  • Chagas disease (*Trypanosoma cruzi*), toxoplasmosis
• toxic: catecholamines, chemotherapy, cocaine
• hypersensitivity/cosinophilic: drugs (antibiotics, diuretics, lithium, clozapine), insect/snake bites
• systemic diseases: collagen vascular diseases (SLE, rheumatoid arthritis, others), sarcoidosis, autoimmune
• other: giant cell myocarditis, acute rheumatic fever

**Signs and Symptoms**

• constitutional symptoms
• acute CHF
• chest pain – due to pericarditis or cardiac ischemia
• arrhythmias
• systemic or pulmonary emboli
• sudden death

---

**REMATCH Trial**

*NEJM* 2001;345:1435-1443

Increased survival of 23% vs. 8% with LVAD vs. medical management of heart failure after 2 yr. Heartmate VAD has a biologic surface therefore does not require long-term anticoagulation but higher risk of infection.
Investigations
- ECG: non-specific ST-T changes ± conduction defects
- blood work
  - increased CK, troponin, LDH, and AST with acute myocardial necrosis ± increased WBC, ESR, ANA, rheumatoid factor, complement levels
  - blood culture, viral titres and cold agglutinins for Mycoplasma
- CXR: enlarged cardiac silhouette
- echo: dilated, hypokinetic chambers, segmental wall motion abnormalities
- cardiovascular magnetic resonance: functional and morphological abnormalities as well as tissue pathology (gadolinium enhancement)
- myocardial biopsy

Management
- supportive care
- restrict physical activity
- treat CHF
- treat arrhythmias
- anticoagulation
- treat underlying cause if possible

Prognosis
- usually self-limited and often unrecognized, many recover
- sudden death in young adults
- may progress to dilated cardiomyopathy

Dilated Cardiomyopathy

Definition
- unexplained dilation and impaired systolic function of one or both ventricles

Etiology
- idiopathic (presumed viral or idiopathic) ~50% of DCM
- alcohol
- familial/genetic
- uncontrolled tachycardia (e.g. persistent rapid AFib)
- collagen vascular disease: SLE, polyarteritis nodosa, dermatomyositis, progressive systemic sclerosis
- infectious: viral (coxsackie B, HIV), Chagas disease, Lyme disease, Rickettsial diseases, acute rheumatic fever, toxoplasmosis
- neuromuscular disease: Duchenne muscular dystrophy, myotonic dystrophy, Friedreich's ataxia
- metabolic: uremia, nutritional deficiency (thiamine, selenium, carnitine)
- endocrine: hyper/hypothyroidism, DM, pheochromocytoma
- peripartum
- toxic: cocaine, heroin, organic solvents
- drugs: chemotherapies (doxorubicin, cyclophosphamide), antiretrovirals, chloroquine, clozapine, TCA
- radiation

Signs and Symptoms
- may present as
  - CHF
  - systemic or pulmonary emboli
  - arrhythmias
  - sudden death (major cause of mortality due to fatal arrhythmia)

Investigations
- blood work: CBC, electrolytes, Cr, bicarbonate, BNP, CK, troponin, LFTs, TSH, TIBC
- ECG: variable ST-T wave abnormalities, poor R wave progression, conduction defects (e.g. BBB), arrhythmias (non-sustained VT)
- CXR: global cardiomegaly (globular heart), signs of CHF, pleural effusion
- echo: chamber enlargement, global hypokinesis, depressed LVEF, MR and TR, mural thrombi
- endomyocardial biopsy: not routine, used to rule out a treatable cause
- coronary angiography: in selected patients to exclude ischemic heart disease

Management
- treat underlying disease: e.g. abstinence from alcohol
- treat CHF: see Heart Failure, C33
- thromboembolism prophylaxis: anticoagulation with warfarin
  - indicated for: AFib, history of thromboembolism or documented thrombus
  - LVEF <30% (controversial)
- treat symptomatic or serious arrhythmias
- immunize against influenza and S. pneumoniae
- consider surgical options (e.g. LVAD, transplant, volume reduction surgery) in appropriate candidates with severe, drug refractory disease
- consider ICD among patients with a LVEF <30%
Prognosis
• depends on etiology
• better with reversible underlying cause, worst with infiltrative diseases, HIV, drug-induced
• cause of death usually CHF (due to pump failure) or sudden death 2° to ventricular arrhythmias
• systemic emboli are significant source of morbidity
• 20% mortality in 1st yr, 10% per year after

Hypertrophic Cardiomyopathy

Definition
• defined as unexplained ventricular hypertrophy
• various patterns of HCM are classified, but most causes involve pattern of septal hypertrophy

Etiology and Pathophysiology
• histopathologic features include myocyte disarray, myocyte hypertrophy, and interstitial fibrosis
• cause is felt to be a genetic defect involving one of the cardiac sarcomeric proteins (>400 mutations associated with autosomal dominant inheritance, incomplete penetrance)
• prevalence of 1/500-1/1,000 in general population
• generally presents in early adulthood

Hemodynamic Classification
• hypertrophic obstructive cardiomyopathy (HOCM): dynamic LV outflow tract (LVOT) obstruction, either at rest or with provocation, defined as LVOT gradient of at least 30 mmHg
• non-obstructive HCM: no LVOT obstruction
• many patients have diastolic dysfunction (impaired ventricular filling secondary to LV hypertrophy which decreases compliance)

Signs and Symptoms
• clinical manifestations: asymptomatic (common, therefore screening is important), SOB on exertion, angina, presyncope/syncope (due to LV outflow obstruction or arrhythmia), CHF, arrhythmias, SCD
• pulses: rapid upstroke, “spike and dome” pattern in carotid pulse (in HCM with outflow tract obstruction)
• precordial palpation: PMI localized, sustained, double impulse, ‘triple ripple’ (triple apical impulse in HOCM), LV lift
• precordial auscultation: normal or paradoxically split S2, S4, harsh systolic diamond-shaped murmur at LSB or apex, enhanced by squat to standing or Valsalva (murmur secondary to LVOT obstruction as compared to AS); often with pansystolic murmur due to mitral regurgitation

Investigations
• ECG/Holter monitor: LVH, high voltages across precordium, prominent Q waves (lead I, aVL, V5, V6), tall R wave in V1, P wave abnormalities
• transthoracic echocardiography and echo-Doppler study: asymmetric septal hypertrophy (less commonly apical), systolic anterior motion (SAM) of mitral valve and MR; LVOT gradient can be estimated by Doppler measurement
• genetic studies (± magnetic resonance imaging) can be helpful when echocardiography is inconclusive for diagnosis
• cardiac catheterization (only when patient being considered for invasive therapy)

Management
• avoid factors which increase obstruction (e.g. volume depletion)
  ▪ avoidance of all competitive sports
• treatment of obstructive HCM
  ▪ medical agents: β-blockers, disopyramide, verapamil (started only in monitored setting), phenylephrine (in setting of cardiogenic shock)
  ▪ avoid nitrates, diuretics, and ACEI as they increase LVOT gradient and worsen symptoms
• patients with obstructive HCM and drug-refractory symptoms
  ▪ surgical myectomy
  ▪ ICD placement
  ▪ septal ethanol ablation
  ▪ dual chamber pacing (rarely done)
• treatment of ventricular arrhythmias: amiodarone or ICD
• first-degree relatives (children, siblings, parents) of patients with HCM should be screened (physical, ECG, 2D echo) every 12-18 mo during during adolescence, then serially every 5 yr during adulthood
Prognosis
- potential complications: AFib, VT, CHF, sudden cardiac death (1% risk/yr; most common cause of SCD in young athletes)
  - major risk factors for sudden death (consider ICD placement)
  - history of survived cardiac arrest/sustained VT
  - family history of multiple premature sudden deaths
  - other factors associated with increased risk of sudden cardiac death
    - syncope (presumed to be arrhythmic in origin)
    - non-sustained VT on ambulatory monitoring
    - marked ventricular hypertrophy (maximum wall thickness ≥30 mm)
    - abnormal BP in response to exercise (in patients <40 yr old with HCM)

Restrictive Cardiomyopathy

Definition
- impaired ventricular filling with preserved systolic function in a non-dilated, non-hypertrophied ventricle secondary to factors that decrease myocardial compliance (fibrosis and/or infiltration)

Etiology
- infiltrative: amyloidosis, sarcoidosis
- non-infiltrative: scleroderma, idiopathic myocardial fibrosis
- storage diseases: hemochromatosis, Fabry’s disease, Gaucher’s disease, glycogen storage diseases
- endomyocardial
  - endomyocardial fibrosis, Loeffler’s endocarditis, or eosinophilic endomyocardial disease
  - radiation heart disease
  - carcinoid syndrome (may have associated tricuspid valve or pulmonary valve dysfunction)

Clinical Manifestations
- CHF (usually with preserved LV systolic function), arrhythmias
- elevated JVP with prominent x and y descents, Kussmaul’s sign
- S3, S4, MR, TR
- thromboembolic events

Investigations
- ECG: low voltage, non-specific, diffuse ST-T wave changes ± non-ischemic Q waves
- CXR: mild cardiac enlargement
- echo: LAE, RAE; specific Doppler findings with no significant respiratory variation
- cardiac catheterization: increased end-diastolic ventricular pressures
- endomyocardial biopsy: to determine etiology (especially for infiltrative RCM)

Management
- exclude constrictive pericarditis
- treat underlying disease: control HR, anticoagulate if AFib
- supportive care and treatment for CHF, arrhythmias
- heart transplant: might be considered for CHF refractory to medical therapy

Prognosis
- depends on etiology

Valvular Heart Disease

Infective Endocarditis
- see Infectious Diseases, ID17
- American Heart Association (AHA) 2007 guidelines recommend IE prophylaxis
  - only for patients with
    - prosthetic valve material
    - past history of IE
    - certain types of congenital heart disease
    - cardiac transplant recipients who develop valvulopathy
  - only for the following procedures
    - dental
    - respiratory tract
    - procedures on infected skin/skin structures/MSK structures
    - not GI/GU procedures specifically
Rheumatic Fever

- see Pediatrics, P60

Prognosis

- acute complications: myocarditis (DCM/CHF), conduction abnormalities (sinus tachycardia, AFib), valvulitis (acute MR), acute pericarditis (not constrictive pericarditis)
- chronic complications: rheumatic valvular heart disease – fibrous thickening, adhesion, calcification of valve leaflets resulting in stenosis/regurgitation, increased risk of IE ± thromboembolism
- onset of symptoms usually after 10-20 yr latency from acute carditis of rheumatic fever
- mitral valve most commonly affected

Valve Repair and Valve Replacement

- indication for valve repair or replacement depends on the severity of the pathology; typically recommended when medical management has failed to adequately improve the symptoms or reduce the risk of morbidity and mortality
- pathologies that may require surgical intervention include congenital defects, infections, rheumatic heart disease as well as a variety of valve diseases associated with aging
- valve repair: balloon valvuloplasty, surgical valvuloplasty (commissurotomy, annuloplasty), chordae tendineae shortening, tissue patch
- valve replacement: typically for aortic or mitral valves only; repair is favored in younger individuals; percutaneous techniques being established

Choice of Valve Prosthesis

A Bedside Clinical Prediction Rule for Detecting Moderate or Severe Aortic Stenosis

**Study Design:** Blinded cross sectional study with 124 patients at an ambulatory cardiology clinic. Patients were examined for: 1) murmur over the right clavicle 2) murmur loudest at second right intercostal space 3) reduced intensity of S2 4) reduced volume of the carotid pulse 5) delayed carotid upstroke.

**Methods:** Patients were examined by blinded investigators and the clinical examination findings were compared to findings on subsequent echocardiography. Moderate to severe aortic stenosis was defined as a valve area <1.2 cm² or a peak intensity gradient of >25 mmHg.

**Results:** Absence of a murmur over the right clavicle ruled out aortic stenosis while presence of ≥3 of the 4 associated symptoms ruled in aortic stenosis (LR+ = 40).

**Conclusions:** Bedside techniques can accurately rule in and rule out moderate to severe aortic stenosis.

Mitral Valve Repair vs. Replacement for Severe Ischemic Mitral Regurgitation

NEJM 2014;370:23-32

**Purpose:** Ischemic mitral regurgitation is associated with significant mortality risk. The purpose of this study was to compare the effectiveness and safety of repairing vs. replacing the mitral valve in patients with severe chronic ischemic mitral regurgitation.

**Study Design:** RCT with 251 patients with severe ischemic mitral regurgitation were randomly assigned to mitral valve repair or chordal-sparing replacement. The primary endpoint was the left ventricular end-systolic volume index (LVESVI) at 12 mo.

**Results:** There were no significant between-group differences in LVESVI, in the rate of major adverse cardiac or cerebrovascular events, in functional status, or in quality of life at 12 mo. The rate of moderate or severe mitral regurgitation recurrence at 12 mo was significantly higher in the repair group than in the replacement group (28.9% vs. 2.3%, respectively).

**Conclusions:** No significant difference in left ventricular reverse remodeling or survival at 12 mo between patients who underwent mitral valve repair or replacement. Replacement provided more durable correction of mitral regurgitation, but there were no significant differences in clinical outcomes.
Table 16. Valvular Heart Disease

Aortic Stenosis (AS)

**Etiology**
Congenital (bicuspid, unicuspid valve), calcification (wear and tear), rheumatic disease

**Definition**
Normal aortic valve area = 3-4 cm²
Mild AS ≤ 1.5 cm²
Moderate AS 1.0 to 1.5 cm²
Severe AS ≤ 1.0 cm²
Critical AS ≤ 0.5 cm²

**Pathophysiology**
Outflow obstruction → increased EDP → concentric LVH → LV failure → CHF
subendocardial ischemia

**Symptoms**
Exertional angina, syncope, dyspnea, PND, orthopnea, peripheral edema

**Physical Exam**
Narrow pulse pressure, brachial-radial delay, pulsatilis parvus et tardus, sustained PMI
Auscultation: crescendo-decrescendo SEM radiating to R clavicle and carotid, musical quality at apex (Gallavardin phenomenon), S4, soft S2 with paradoxical splitting, S3 (late)

**Investigations**
ECG: LVH and strain, LBBD, LAFib
CXR: post-stenotic aortic root dilatation, calcified valve, LVH, LAE, CHF
Echocardiography: reduced valve area, pressure gradient, LVH, reduced LV function

**Treatment**
Asymptomatic: serial echos, avoid exertion
Symptomatic: avoid nitrates/arterial dilators and ACEI in severe AS
Surgery if: symptomatic or LV dysfunction

**Surgical Options**
Valve replacement: aortic valve disease and trileaflet valve
– prior to pregnancy (if AS significant)
– balloon valvuloplasty (in very young)

**Interventional Options**
Percutaneous valve replacement (transfemoral or transapical approach)
is an option in selected patients who are not considered good candidates for surgery

Mitraille Stenosis (MS)

**Etiology**
Rheumatic disease most common cause, congenital (rare)

**Definition**
Severe MS is mitral valve area (MVA) <1.2 cm²

**Pathophysiology**
MS → fixed CO and LAE → increased LA pressure → pulmonary vascular resistance and CHF; worse with Afib (no atrial kick), tachycardia (decreased atrial emptying time) and pregnancy (increased preload)

**Symptoms**
SGB on exertion, orthopnea, fatigue, palpitations, peripheral edema, malar flush, pinched and blue facies (severe MS)

**Physical Exam**
Afib, no “a” wave on JVP, left parasternal lift, palpable diastolic thrill at apex
Auscultation: mid-diastolic rumble at apex, best heard with bell in left lateral decubitus position following exertion, loud S1, OS following loud P2 (heard before diastolic murmur), long diastolic murmur and short A2 OS interval correlate with worse MS

**Investigations**
ECG: NSR/Afib, LAE (P mitrale), RVH, RAD
CXR: LAFib, CHF; mitral valve calcification
Echo/TEE: shows restricted opening of mitral valve
Cath: indicated in concurrent CAD if >40 yr (male) or >50 yr (female)

**Treatment**
Avoid exertion, fever (increased LA pressure), treat Afib and CHF, increase diastolic filling time (i-blockers, digitalis)
Surgery if: NYHA class III-IV CHF, LV dilatation/aneurysm (CHF, DCM, myocarditis), IE abscess, Marfan’s syndrome, HOCM, acute MI, myxoma, mtrval valve annulus calcium, chordae/papillary muscle trauma/ischemia/rupture (acute), rheumatic disease

**Pathophysiology**
Reduced CO → increased LV and LA pressure → LV and LA dilatation → CHF and pulmonary HTN

**Symptoms**
Dyspnea, PND, orthopnea, palpitations, peripheral edema

**Physical Exam**
Displaced hyperdynamic apex, left parasternal lift, apical thrill
Auscultation: holosystolic murmur at apex, radiating to axilla ± mid-diastolic rumble, loud S2 (if pulmonary HTN), S3

**Investigations**
ECG: LAE, left atrial delay (bifid P waves), ± LVH
CXR: LVH, LAE, pulmonary venous HTN
Echo: etiology and severity of MR, LV function, leaflets
Swan-Ganz Catheter: prominent LA “v” wave

**Treatment**
Asymptomatic: serial echos
Symptomatic: decrease preload (diuretics), decrease afterload (ACEI) for severe MR and poor surgical candidates; stabilize acute MR with vasodilators before surgery
Surgery if: acute MR with CHF, papillary muscle rupture, NYHA class III-IV CHF, AF; increasing LV size or worsening LV function, earlier surgery if valve repairable (> 90% likelihood) and patient is low-risk for surgery

**Surgical Options**
Valve repair: >75% of pts with MR and myxomatous mitral valve prolapse – annuloplasty rings, leaflet repair, chordae transfers/shorten/replacement
Valve replacement: failure of repair, heavily calcified annulus
Advantage of repair: lower rate of endocarditis, no anticoagulation, less chance of re-operation

Aortic Regurgitation (AR)

**Etiology**
Supravalvular: aortic root disease
(Marfan’s, atherosclerosis and dissecting aneurysm, connective tissue disease)
Valvular: congenital (bicuspid aortic valve, large VSD), IE

**Pathophysiology**
Volume overload → LV dilatation → increased SV, high sBP and low dBP → increased wall tension → pressure overload → LVH (low dBP → decreased coronary perfusion)

**Symptoms**
Usually only becomes symptomatic late in disease when LV failure develops
Dyspnea, orthopnea, PND, syncope, angina

**Physical Exam**
Waterhammer pulse, bisferiens pulse, femoral-brachial sBP >20 (Hill’s test wide pulse pressure), hyperdynamic apex, displaced PMI, heaving apex
Auscultation: early decrescendo diastolic murmur at LLSS (cusp pathology) or RLSB (aortic root pathology), best heard sitting, leaning forward, on full expiration, soft S1, absent S2, S3 (late)

**Investigations**
ECG: LVH, LAE
CXR: LVH, LAE, aortic root dilatation
Echo/TTE: quantify AR, leaflet or aortic root anomalies
Cath: if >40 yr and surgical candidate – to assess for ischemic heart disease

**Exercise Testing**
Hypertension with exercise

**Treatment**
Asymptomatic: serial echos, afterload reduction (e.g. ACEI, nifedipine, hydralazine)
Symptomatic: avoid exertion, treat CHF
Surgery if: NYHA class III-IV CHF; LV dilatation and/or LVF <50% with/without symptoms

**Surgical Options**
Valve replacement: most patients
Valve repair: very limited role

Aortic root replacement (Bentall procedure):
– when ascending aortic aneurysm present, valved conduit used

Mitraille Regurgitation (MR)

**Etiology**
Mitraille valve prolapse, congenital cleft leaflet, LV dilatation/aneurysm (CHF, DCM, myocarditis), IE abscess, Marfan’s syndrome, HOCM, acute MI, myxoma, mtrval valve annulus calcium, chordae/papillary muscle trauma/ischemia/rupture (acute), rheumatic disease

**Pathophysiology**
Reduced CO → increased LV and LA pressure → LV and LA dilatation → CHF and pulmonary HTN

**Symptoms**
Dyspnea, PND, orthopnea, palpitations, peripheral edema

**Physical Exam**
Displaced hyperdynamic apex, left parasternal lift, apical thrill
Auscultation: holosystolic murmur at apex, radiating to axilla ± mid-diastolic rumble, loud S2 (if pulmonary HTN), S3

**Investigations**
ECG: LAE, left atrial delay (bifid P waves), ± LVH
CXR: LVH, LAE, pulmonary venous HTN
Echo: etiology and severity of MR, LV function, leaflets
Swan-Ganz Catheter: prominent LA “v” wave

**Treatment**
Asymptomatic: serial echos
Symptomatic: decrease preload (diuretics), decrease afterload (ACEI) for severe MR and poor surgical candidates; stabilize acute MR with vasodilators before surgery
Surgery if: acute MR with CHF, papillary muscle rupture, NYHA class III-IV CHF, AF; increasing LV size or worsening LV function, earlier surgery if valve repairable (> 90% likelihood) and patient is low-risk for surgery

**Surgical Options**
Valve repair: >75% of pts with MR and myxomatous mitral valve prolapse – annuloplasty rings, leaflet repair, chordae transfers/shorten/replacement
Valve replacement: failure of repair, heavily calcified annulus
Advantage of repair: lower rate of endocarditis, no anticoagulation, less chance of re-operation

</tbody>
</table>

---

**Tricuspid Stenosis (TS)**
- **Etiology**: Rheumatic disease, congenital, carcinoid syndrome, fibroelastosis; usually accompanied by MS
- **Pathophysiology**: Increased RV pressure → right heart failure → decreased CO and fixed on exertion
- **Symptoms**: Perihypertrophy → right heart failure
- **Physical Exam**: Prominent “a” waves in JVP; +ve abdominojugular reflux, Kussmaul’s sign, diastolic rumble 4th left intercostal space
- **Investigations**: ECG: RAE; CXR: dilatation of RA without pulmonary artery enlargement; Echo: diagnostic
- **Treatment**: Preload reduction (diuretics), slow HR; Surgery: if: only if other surgery required (e.g. mitral valve replacement)
- **Surgical Options**: Valve Replacement:
  - if severely diseased valve
  - bioprosthesis preferred

---

**Pulmonary Stenosis (PS)**
- **Etiology**: Usually congenital, rheumatic disease (rare), carcinoid syndrome
- **Pathophysiology**: Increased RV pressure → RV hypertrophy → right heart failure
- **Symptoms**: Chest pain, syncope, fatigue, peripheral edema
- **Physical Exam**: Systolic murmur at 2nd left intercostal space accentuated by inspiration, pulmonary ejection click, right-sided S4
- **Investigations**: ECG: RVH; CXR: prominent pulmonary arteries enlarged RV; Echocardiogram: diagnostic
- **Treatment**: Balloon valvuloplasty if severe symptoms
- **Surgical Options**: Percutaneous or open balloon valvuloplasty

---

**Tricuspid Regurgitation (TR)**
- **Etiology**: RV dilatation, IE (particularly due to IV drug use), rheumatic disease, congenital (Ebstein anomaly), carcinoid
- **Pathophysiology**: RV dilatation → TR → further RV dilatation → right heart failure
- **Symptoms**: Perihypertrophy; fatigue, peripheral edema
- **Physical Exam**: “c” waves in JVP; +ve abdominojugular reflux, Kussmaul’s sign, holosystolic murmur at LLSB accentuated by inspiration, left parasternal lift
- **Investigations**: ECG: RAE, RVH, AFib; CXR: RAE, RV enlargement; Echocardiogram: diagnostic
- **Treatment**: Preload reduction (diuretics); Surgery: if: only if other surgery required (e.g. mitral valve replacement)
- **Surgical Options**: Annuloplasty (i.e. repair, rarely done)

---

**Mitral Valve Prolapse (MVP)**
- **Etiology**: Myxomatous degeneration of chordae, thick, bulky leaflets that crowd orifice, associated with Marfan’s syndrome, pectus excavatum, straight back syndrome, other MSK abnormalities; <3% of population
- **Pathophysiology**: Mitral valve displaced into LA during systole; no causal mechanisms found for symptoms
- **Symptoms**: Prolonged, stabbing chest pain, dyspnea, anxiety/panic, palpitations, fatigue, presyncope
- **Physical Exam**: Auscultation: mid-systolic click (due to billowing of mitral leaflet into LA; tensing of redundant valve tissue); mid to late systolic murmur at apex, accentuated by Valsalva or squat-to-stand maneuvers
- **Investigations**: ECG: non-specific ST-T wave changes, paroxysmal SVT, ventricular ectopy; Echocardiogram: systolic displacement of thickened mitral valve leaflets into LA
- **Treatment**: Asymptomatic: no treatment; reassurance
- **Symptomatic**: β-blockers and avoidance of stimulants (caffeine) for significant palpitations, anticoagulation if AFib
- **Surgical Options**: Mitral valve surgery (repair favored over replacement) if symptomatic and significant MR:

---

**Pulmonary Regurgitation (PR)**
- **Etiology**: Pulmonary HTN, IE, rheumatic disease, tetrology of Fallot (post-repair)
- **Pathophysiology**: Increased RV volume → increased wall tension → RV hypertrophy → right heart failure
- **Symptoms**: Chest pain, syncope, fatigue, peripheral edema
- **Physical Exam**: Early diastolic murmur at LLSB, Graham Steell (diastolic) murmur 2nd and 3rd left intercostal space increasing with inspiration
- **Investigations**: ECG: RVH; CXR: prominent pulmonary arteries if pulmonary HTN; enlarged RV; Echocardiogram: diagnostic
- **Treatment**: Rarely requires treatment; valve replacement (rarely done)
- **Surgical Options**: Pulmonary valve replacement
Figure 39. Hemodynamics of aortic stenosis
Stenosis across the aortic valve results in the generation of a significant pressure gradient between the left ventricle and the aorta and a crescendo-decrescendo murmur during systolic contraction. The stenosis decreases the intensity of aortic valve closure hence diminishing S2.

Figure 40. Hemodynamics of aortic regurgitation
Regurgitation across the aortic valve during diastole causes the aortic pressure to rapidly decrease and a decrescendo murmur can be heard at the onset of diastole (after S2 is audible). The presence of regurgitant blood from the aorta increases left-ventricular end-diastolic volume.

Figure 41. Hemodynamics of acute mitral regurgitation
During systolic contraction, blood regurgitates from the left ventricle into the left atrium across the incompetent mitral valve resulting in an audible holosystolic murmur between S1 and S2. The portion of left ventricular end-diastolic volume that regurgitates into the left atrial myocardium increases left atrial pressures resulting in a tall V-wave (in the JVP).

Figure 42. Hemodynamics of mitral stenosis
First note that the left atrial pressure exceeds the left ventricular pressure during diastole due to mitral stenosis and the consequent generation of a pressure gradient across the left atrium and left ventricle. In diastole the stenotic mitral valve opens which corresponds to the opening snap (OS) and the passage of blood across the mitral stenosis results in an audible decrescendo murmur. Left atrial contraction prior to S1 increases the pressure gradient resulting in accentuation of the murmur before S1 is audible.
Pericardial Disease

Acute Pericarditis

Etiology of Pericarditis/Pericardial Effusion
- idiopathic is most common: presumed to be viral
- infectious
  - viral: Coxsackie virus A, B (most common), echovirus
  - bacterial: *S. pneumoniae, S. aureus*
  - TB
  - fungal: histoplasmosis, blastomycosis
- post-MI: acute (direct extension of myocardial inflammation, 1-7 d post-MI), Dressler's syndrome (autoimmune reaction, 2-8 wk post-MI)
- post-cardiac surgery (e.g. CABG), other trauma
- metabolic: uremia (common), hypothyroidism
- neoplasm: Hodgkin's, breast, lung, renal cell carcinoma, melanoma
- collagen vascular disease: SLE, polyarteritis, rheumatoid arthritis, scleroderma
- vascular: dissecting aneurysm
- other: drugs (e.g. hydralazine), radiation, infiltrative disease (sarcoid)

Signs and Symptoms
- diagnostic triad: chest pain, friction rub, and ECG changes
- pleuritic chest pain: alleviated by sitting up and leaning forward
- pericardial friction rub: may be uni-, bi-, or triphasic
- ± fever, malaise

Investigations
- ECG: initially diffuse elevated ST segments ± depressed PR segment, the elevation in the ST segment is concave upwards → 2-5 d later ST isoelectric with T wave flattening and inversion
- CXR: normal heart size, pulmonary infiltrates
- echo: performed to assess for pericardial effusion

Treatment
- treat the underlying disease
- anti-inflammatory agents (high dose NSAIDs/ASA, colchicine; steroids use controversial), analgesics

Complications
- recurrent episodes of pericarditis, atrial arrhythmia, pericardial effusion, tamponade, constrictive pericarditis

Pericardial Effusion

Etiology
- transudative (serous)
  - CHF, hypoalbuminemia/hypoproteinemia, hypothyroidism
- exudative (serosanguinous or bloody)
  - causes similar to the causes of acute pericarditis
  - may develop acute effusion secondary to hemopericardium (trauma, post-MI myocardial rupture, aortic dissection)
- physiologic consequences depend on type and volume of effusion, rate of effusion development, and underlying cardiac disease

Signs and Symptoms
- may be asymptomatic or similar to acute pericarditis
- dyspnea, cough
- extra-cardiac (esophageal/recurrent laryngeal nerve/tracheo-bronchial/phrenic nerve irritation)
- JVP increased with dominant “x” descent
- arterial pulse normal to decreased volume, decreased pulse pressure
- auscultation: distant heart sounds ± rub
- Ewart's sign

Investigations
- ECG: low voltage, flat T waves, electrical alternans
- CXR: cardiomegaly, rounded cardiac contour
- echo (procedure of choice): fluid in pericardial sac
- pericardiocentesis: definitive method of determining transudate vs. exudate, identify infectious agents, neoplastic involvement

Treatment
- mild: frequent observation with serial echos, treat underlying cause, anti-inflammatory agents
- severe: treat as in tamponade

Acute Pericarditis Triad
- Chest pain
- Friction rub
- ECG changes

Ewart's Sign
Bronchial breathing and dullness to percussion at the lower angle of the left scapula in pericardial effusion due to effusion compressing left lower lobe of lung.
Cardiac Tamponade

Etiology
- major complication of rapidly accumulating pericardial effusion
- cardiac tamponade is a clinical diagnosis
- any cause of pericarditis but especially trauma, malignancy, uremia, proximal aortic dissection with rupture

Pathophysiology
- high intra-pericardial pressure → decreased venous return → decreased diastolic ventricular filling → decreased CO → hypotension and venous congestion

Signs and Symptoms
- tachypnea, dyspnea, shock, muffled heart sounds
- pulsus paradoxus (inspiratory fall in systolic BP >10 mmHg during quiet breathing)
- JVP "x" descent only, blunted "y" descent
- hepatic congestion/peripheral edema

Investigations
- ECG: electrical alternans (pathognomonic variation in R wave amplitude), low voltage
- echo: pericardial effusion, compression of cardiac chambers (RA and RV) in diastole
- cardiac catheterization

Treatment
- pericardiocentesis – echo-guided
- pericardiotomy
- avoid diuretics and vasodilators (these decrease venous return to already under-filled RV → decrease LV preload → decrease CO)
- IV fluid may increase CO
- treat underlying cause

Constrictive Pericarditis

Etiology
- chronic pericarditis resulting in fibrosed, thickened, adherent, and/or calcified pericardium
- any cause of acute pericarditis may result in chronic pericarditis
- major causes are idiopathic, post-infectious (viral, TB), radiation, post-cardiac surgery, uremia, MI, collagen vascular disease

Signs and Symptoms
- dyspnea, fatigue, palpitations
- abdominal pain
- may mimic CHF (especially right-sided HF)
  ▪ ascites, hepatosplenomegaly, edema
- increased JVP, Kussmaul’s sign (paradoxical increase in JVP with inspiration), Friedreich’s sign (prominent "y" descent)
- BP usually normal (and usually no pulsus paradoxus)
- precordial examination: ± pericardial knock (early diastolic sound)
- see Table 17 for differentiation from cardiac tamponade

Investigations
- ECG: non-specific – low voltage, flat T wave, ± AFib
- CXR: pericardial calcification, effusions
- echo/CT/MRI: pericardial thickening
- cardiac catheterization: equalization of end-diastolic chamber pressures (diagnostic)

Treatment
- medical: diuretics, salt restriction
- surgical: pericardiectomy (only if refractory to medical therapy)
- prognosis best with idiopathic or infectious cause and worst in post-radiation; death may result from heart failure

General Principles

Drug Nomenclature

- **chemical name**: describes chemical structure; same in all countries (e.g. \(N\)-(4-hydroxyphenyl)acetamide is acetaminophen)
- **DIN or NDC**: DIN assigned by Health Canada; NDC assigned by FDA (US)
- **non-proprietary name**: approved name (post-phase III trial), official name (listed in pharmacopoeia), or generic name (off-patent) (e.g. acetaminophen)
- **proprietary (trade) name**: the brand name or registered trademark (e.g. Tylenol®)

Phases of Clinical Testing

- **phase I**: first administration to healthy human volunteers, following animal studies; to determine PK and PD
- **phase II**: first administration to patients, small sample sizes; to determine initial safety and effectiveness, dose range, PK, PD
- **phase III**: large sample sizes, often double-blind RCT; comparative (new drug vs. placebo or standard of care) to establish safety and efficacy
- **phase IV**: post-marketing surveillance, wide distribution; to determine rare ADRs, effects of long-term use, ideal dosing, effects in real world practice

Drug Administration

- choice of route of administration depends on: drug properties, local and systemic effects (limiting action or adverse events), desired onset and/or duration of action, patient characteristics

Table 1. Routes of Drug Administration

<table>

</tbody>
</table>
Pharmacokinetics

- study of “what the body does to a drug”
- definition: relationship between drug administration, time-course/rate of absorption and distribution, concentration changes in the body compartments, and the drug’s removal from the body

Absorption

- definition: movement of the drug from the site of administration into plasma

Mechanisms of Drug Absorption

- most drugs are absorbed into the systemic circulation via passive diffusion
- other mechanisms: active transport, facilitated diffusion, pinocytosis/phagocytosis

Factors Affecting the Rate and Extent of Drug Absorption

- Po/w (i.e. its relative solubility in oil/lipid vs. water)
- local blood flow at the site of administration (e.g. sublingual vessels facilitate rapid absorption of SL medications)
- molecular size (e.g. small molecular weight drugs absorb faster)
- pH and drug ionization
  - drugs are usually weak acids (e.g. ASA) or weak bases (e.g. ketoconazole) and thus have both ionized and non-ionized forms
  - body compartment pH and drug pKa determine the ratio of ionized:non-ionized ratio (using the Henderson-Hasselbach equation)
  - non-ionized forms cross cell membranes much faster than ionized (charged) forms
- total surface area for absorption
  - small intestinal villi (large surface area) is the primary site of absorption for most oral drugs

Bioavailability

- definition: fraction of dose after administration that reaches systemic circulation in an unchanged state
- decreased by: drug absorption, gut metabolism, and hepatic first-pass effect
- IV dose has 100% bioavailability (F = 1)

First-Pass Effect

- definition: drug metabolism by the liver and sometimes the gut before it reaches systemic circulation, resulting in reduced F
- occurs with PO administration of a drug: GI tract (absorption) → portal vein to liver (first-pass metabolism) → systemic circulation
- occurs to much lesser extent with PR administration because drug absorbed in colon bypasses the portal system: colon (absorption) → internal pudendal veins → IVC → systemic circulation

Efflux Pump

- Pgp is a protein in the GI tract, renal epithelium, and elsewhere that acts as a multidrug efflux pump involved in the transport of drugs out of cells
- acts to oppose intestinal absorption and enhance renal elimination of certain drugs (e.g. digoxin, dabigatran, etexilate, etoposide, paclitaxel, tacrolimus, cyclosporine)
- some drugs (e.g. macrolide antibiotics) inhibit Pgp function, leading to increased levels of Pgp substrates; Pgp inducers (e.g. St. John’s wort) do the opposite
- some tumors overexpress Pgp leading to multidrug resistance to chemotherapy agents

Distribution

- definition: movement of drugs between different body compartments and to the site of action
- major body fluid compartments: plasma, interstitial fluid, intracellular fluid, transcellular fluid (e.g. CSF, peritoneal, pleural)
- tissue compartments: fat, brain
Factors Affecting the Rate and Extent of Drug Distribution
- physiochemical properties of the drug (e.g. $P_{ow}$)
- pH of fluid
- plasma protein binding
- binding within compartments (i.e. depots)
- regional blood flow

Volume of Distribution
- maximum actual $V_d$ (anatomic fluid volume accessible to drug) = TBW (TBW~40 L for average adult)
- $V_d$: the apparent volume of fluid into which a drug dissolves
  - a calculated value = amount of drug in body ÷ plasma drug concentration
  - a theoretical value that does not correspond to an anatomical space (i.e. can exceed TBW)
  - small $V_d$ corresponds to a drug which concentrates in plasma and/or binds plasma proteins to a high degree
  - large $V_d$ corresponds to a drug that distributes into tissues (fat, muscle, etc.); most is not in blood (measured) space, and it therefore “appears” to distribute in a large volume
- $V_d$ of plasma-protein bound drugs can be altered by liver and kidney disease
- example: amiodarone distributes into TBW (actual $V_d = 40$ L), but it also concentrates in fat tissues giving instead an apparent $V_d$ of 400 L; therefore, to achieve a given plasma concentration of amiodarone, we dose as though the drug distributes into 400 L of body fluid

Plasma Protein Binding
- drug molecules in the blood exist in an equilibrium of two forms:
  1. bound to plasma protein: acidic drugs bind to albumin, basic drugs bind to α1-acid glycoprotein
  2. free or unbound: can leave the circulation to distribute into tissues and exert an effect, subject to metabolism and elimination
- bound fraction is determined by drug concentration, binding affinity, and plasma protein concentration (number of binding sites)
- reduced number of binding sites (e.g. hypoalbuminemia) or saturation of binding sites (e.g. competition/displacement) may result in an increased concentration of free drug, which is often metabolized with no harmful effects, although toxicity is possible

Depots
- a body compartment where drug molecules tend to be stored and released slowly over a long period of time
- fat is a depot for very lipid soluble drugs (e.g. diazepam)
- some oil-based medications are injected IM for slow release (e.g. depot medroxyprogesterone acetate q3mo; depot risperidone q2wk)

Barriers (Relative)
- body structures that limit or prevent diffusion of drug molecules, such as the placenta or BBB (a barrier composed of tight junctions between capillary endothelial cells and astrocytes)
- many of these barriers result, in part, from the activity of multidrug efflux pumps (e.g. Pgp), which serve as a natural defense mechanism against drugs and xenobiotics
- need to consider dosing route if drugs are meant to cross these barriers

Metabolism (Biotransformation)
- definition: chemical transformation of a drug in vivo to make it more hydrophilic to enhance renal elimination
- sites of biotransformation: liver (main), GI tract, lung, plasma, kidney
- as a result of the process of biotransformation
  - a pro-drug may be activated (e.g. tamoxifen to endoxifen; codeine to morphine)
  - a drug may be changed to another active metabolite (e.g. diazepam to oxazepam)
  - a drug may be changed to a toxic metabolite (e.g. meperidine to normeperidine)
  - a drug may be inactivated (most drugs)
Drug Metabolizing Pathways
- **phase I (P450) reactions**
  - small molecular changes introduce or unmask polar chemical groups on a parent compound to increase its water solubility (e.g. oxidation-reduction, hydrolysis, hydroxylation); the change in \( P_{w/w} \) is typically minimal compared to phase II, and often phase I places a polar "handle" on a lipophilic drug to allow for phase II
  - mediated by CYPs found in the endoplasmic reticulum
  - product of the reaction can be excreted or undergo further phase II reactions

- **phase II (conjugation) reactions**
  - conjugation with large polar endogenous substrates (e.g. glucuronidation, glutathione conjugation, sulfation)
  - dramatically increases water solubility and renal elimination
  - sometimes results in biologically active metabolites (e.g. glucuronides of morphine)
  - can occur independently of phase I reactions

Factors Affecting Drug Biotransformation
- **genetic polymorphism** of metabolizing enzymes
  - individual genotypes may determine rate of drug metabolism (e.g. poor, intermediate, extensive, or ultrarapid metabolizers)
  - may lead to toxicity or ineffectiveness of a drug at a normal dose
    - tamoxifen and codeine are prodrugs activated by CYP2D6 (nonfunctional alleles reduce effectiveness, whereas overactive/duplicated alleles impart "ultrarapid metabolizer" phenotype)
    - warfarin is metabolized by CYP2C9 (nonfunctional alleles lead to greater effect and lower dose requirements)
- **enzyme inhibition** may sometimes be due to other drugs
  - CYP inhibition leads to an increased concentration and bioavailability of the substrate drug (e.g. erythromycin [CYP3A4 inhibitor], can predispose patients to simvastatin toxicity [metabolized by CYP3A4])
- **enzyme induction**
  - certain medications enhance gene transcription leading to an increase in the activity of a metabolizing enzyme
    - a drug may induce its own metabolism (e.g. carbamazepine) or that of other drugs (e.g. phenobarbital can induce the metabolism of OCP and bilirubin) by inducing the CYP system
  - **liver dysfunction** (e.g. hepatitis, alcoholic liver, biliary cirrhosis, or hepatocellular carcinoma) may decrease drug metabolism but this may not be clinically significant due to the liver’s reserve capacity
  - **renal disease** often results in decreased drug clearance
  - **extremes of age** (neonates or elderly) have reduced biotransformation capacity, and doses should be adjusted accordingly
  - **nutrition**: insufficient protein and fatty acid intake decreases CYP biotransformation, and vitamin/mineral deficiencies may also impact metabolizing enzymes
  - **alcohol**: while acute alcohol ingestion inhibits CYP2E1, chronic consumption can induce CYP2E1 and increase the risk of hepato cellular damage from acetaminophen by increasing the generation of acetaminophen’s toxic metabolite
  - **smoking**: can induce CYP1A2, thus increasing the metabolism of some drugs (e.g. theophylline)

Elimination
- definition: removal of drug from the body

Routes of Drug Elimination
- **kidney** (main organ of elimination): two mechanisms
  1. **glomerular filtration**
    - a passive process, so that only the free drug fraction can be filtered
    - drug filtration rate depends on GFR, degree of protein binding of drug, and size of drug
  2. **tubular secretion**
    - an active process that is saturable, allowing both protein-bound and free drug fractions to be excreted
    - distinct transport mechanisms for weak acids (e.g. penicillin, salicylic acid, probenecid, chlorothiazide) and weak bases (e.g. quinine, quaternary ammonium compounds such as choline)
    - drugs may competitively block mutual secretion if both use the same secretion system (e.g. probenecid can be used to reduce the excretion of penicillin)
- **tubular reabsorption**: drugs can be passively reabsorbed back to the systemic circulation, counteracting elimination mechanisms
- **renal function** (decreases with age and is affected by many disease states) is assessed clinically using serum Cr levels
- **stool**: some drugs and metabolites are actively excreted in the bile (e.g. corticosteroids) or directly into the intestinal tract
  - enterohepatic reabsorption counteracts stool elimination, and thus can substantially prolong the drug’s duration in the body
  - some glucuronic acid conjugates that are excreted in the bile will be hydrolyzed in the intestines by bacteria back to its original form that can be systemically reabsorbed
- **lungs**: elimination of anesthetic gases and vapours by exhalation
- **saliva**: saliva concentrations of some drugs parallel their plasma levels (e.g. rifampin)

### Pharmacokinetic Calculation

- **definition**: the quantitative description of the rates of the various steps of drug disposition (i.e. how drugs move through the body)
- the pharmacokinetic principles of ADME (absorption, distribution, metabolism, and elimination) can be graphically represented on a concentration vs. time graph

### Time-Course of Drug Action

- many kinetic parameters are measured using IV dosing, such that absorption is immediate and distribution for most drugs is rapid; thus elimination is the main process being measured
- the concentration axis is converted to a log10 concentration to allow for easier mathematical calculations

#### Half-Life

- **definition**: time taken for the serum drug level to fall 50% during elimination
- drugs with first order kinetics require five half-lives to reach steady state with repeated dosing or for complete drug elimination once dosing is stopped

<table>
<thead>
<tr>
<th># of Half-Lives</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>3.3</th>
<th>4</th>
<th>5</th>
</tr>
</thead>
<tbody>
<tr>
<td>% of Steady State Concentration</td>
<td>50%</td>
<td>75%</td>
<td>87.5%</td>
<td>90%</td>
<td>93.8%</td>
<td>96.9%</td>
</tr>
</tbody>
</table>

### Steady State

- drug concentration stays constant when the same amount of drug entering the system is eliminated from the system
- appropriate timing is important for therapeutic monitoring since drug levels are reliable only when the drug has reached steady state
- **special situations**
  - use a loading dose for drugs with a long half-life and when there is clinical need to rapidly achieve therapeutic levels (e.g. amiodarone, digoxin, phenytoin)
  - use continuous infusion for drugs with a very short half-life and when there is need for a long-term effect and multiple or frequently repeated doses are too inconvenient (e.g. nitroprusside, insulin, unfractionated heparin)

### Clearance

- a quantitative measurement of the body fluid volume from which a substance is removed per unit time
- Cl = rate of elimination of drug / plasma drug concentration
- must consider Cl from a specific part of the body and total body Cl

### Elimination Kinetics

- **first-order kinetics** (most common type)
  - constant fraction of drug eliminated per unit time
  - some drugs can follow first-order kinetics until elimination is saturated (usually at large doses) at which point the Cl decreases
  - becomes linear relationship when plotted on a log(concentration) vs. time graph
- **zero-order kinetics** (less common, associated with toxicities, e.g. alcohol)
  - a constant rate of drug eliminated regardless of concentration; concept of half-life does not apply
  - the concentration axis is converted to a log (concentration) to allow for easier mathematical calculations

### The Cockcroft-Gault Equation

Estimate CrCl in Adults 20 yr of age and older

- For males
  \[ \text{CrCl (mL/min)} = \left( \frac{140 - \text{age in yr}}{\text{Weight (kg)}} \times 1.2 \right) \times \text{serum Cr (µmol/L)} \]
- For females, multiply above equation by 0.85
- Only applies when renal function is at steady state

### Principles of Pharmacokinetics

- **Vd** = amount of drug in the body / plasma drug concentration
- **Cl** = rate of elimination of drug / plasma drug concentration
- **Half-life** (t½) = 0.7xVd/Cl

For most drugs it takes 5 half-lives to reach steady state with repeated dosing or to eliminate a drug once dosing is stopped
### Pharmacodynamics

#### Dose-Response Relationship

**Efficacy**
- the ability of a drug to produce a response after binding to its cognate receptor
- measured by \( E_{\text{max}} \) (the maximal response that a drug can elicit in a RCT or under optimal circumstances)

**Potency**
- measured by \( EC_{50} \) (the concentration of a drug needed to produce 50% of \( E_{\text{max}} \))
- a drug that reaches its \( EC_{50} \) at the lower dose is more potent

![Figure 6. log(dose)-response curve illustrating efficacy and potency](image)

**Effects of Drugs on Receptors**

**Agonists**
- drugs that have both affinity and efficacy for their cognate receptors
  - **affinity**: the ability of the agonist to bind to the receptor (e.g. the \( \beta_2 \)-agonist salbutamol has greater affinity for \( \beta_2 \)-receptors than \( \beta_1 \)-receptors)
  - **efficacy**: the ability to recapitulate endogenous response via the receptor interaction (e.g. binding of salbutamol to \( \beta_2 \)-receptors results in smooth muscle relaxation)
- **full agonists**: can elicit a maximal effect at a receptor
- **partial agonists**: can only elicit a partial effect, no matter how high the concentration (i.e. reduced efficacy compared to full agonists) at the receptor

**Antagonists**
- drugs that block the action of an agonist or of an endogenous ligand
  - **chemical antagonism**: direct chemical interaction between agonist and antagonist prevents agonist-receptor binding (e.g. chelating agents for removal of heavy metals)
  - **functional antagonism**: two agonists that act independently at different receptors and have opposite physiological effects (e.g. acetylcholine at the muscarinic receptor compared to epinephrine at the adrenergic receptor)
- **reversible competitive and irreversible antagonism**
  - drugs that have affinity but no efficacy for their cognate receptors, and therefore, exert no effect upon binding
  - reversible competitive antagonists reversibly bind to the same receptor as the agonist, thus displacing it (e.g. naloxone is an antagonist to morphine or heroin)
irreversible antagonists irreversibly bind to the same receptor as the agonist, blocking it from binding (e.g. phenoxybenzamine forms a permanent covalent bond with adrenergic receptors preventing adrenaline and NE from binding)

- **non-competitive antagonism**
  - antagonists bind to an alternate site separate but near the agonist site, producing allosteric effects that change the ability of the agonist to bind (e.g. organophosphates irreversibly bind acetylcholinesterase)

Effectiveness and Safety

**Effectiveness**
- $ED_{50}$ (Effective Dose): the dose of a drug needed to cause a therapeutic effect in 50% of a test population of subjects

**Safety**
- $LD_{50}$ (Lethal Dose): the dose of a drug needed to cause death in 50% of a test population of subjects
- $TD_{50}$ (Toxic Dose): the dose needed to cause a harmful effect in 50% of a test population of subjects
**Therapeutic Indices**

**Therapeutic Index: \( \text{TD}_{50}/\text{ED}_{50} \)**
- reflects the “margin of safety” for a drug – the likelihood of a therapeutic dose to cause serious toxicity or death
- the larger the TI, the safer a drug (e.g. warfarin has a narrow TI and requires accurate therapeutic monitoring)
- factors that can change the TI
  - presence of interacting drugs
  - changes in drug absorption, distribution, metabolism, elimination

**Certain Safety Factor: \( \text{TD}_{1}/\text{ED}_{99} \)**
- CSFa >1 translates to a dose effective in at least 99% of the population and toxic in less than 1% of the population

---

**Therapeutic Drug Monitoring**

- definition: using serum drug concentration data to optimize drug therapy (e.g. dose adjustment, monitor compliance)
  - serum drug samples are usually taken when the drug has reached steady state (after approximately 5 half-lives)
  - TDM is often used for drugs that have: narrow TIs, unpredictable dose-response relationships, significant consequences associated with therapeutic failure or toxicity, wide inter-patient pharmacokinetic variability

**Adverse Drug Reactions**

**Table 3. Characteristics of Type A-E Adverse Drug Reactions**

---

In the US, 700,000 emergency department visits and 120,000 hospitalizations are due to ADRs annually.
Approach to Suspected Adverse Drug Reactions

- history and physical exam: signs and symptoms of the reaction (e.g. rash, fever, hepatitis, anaphylaxis), timing, risk factors, detailed medication history including all drugs and timing, dechallenge (response when drug is removed) and rechallenge (response when drug is given again)
- differentiate between drug therapy vs. disease pathophysiology
- treatment: stop the drug, supportive care, symptomatic relief
- resources: check recent literature, FDA; contact the pharmaceutical company; call Poison Control (1-800-222-1222) if overdose or poisoning suspected; check with Motherisk (www.motherisk.org) in cases involving pregnant or breastfeeding women
- report all suspected ADRs that are: 1) unexpected, 2) serious, or 3) reactions to recently marketed drugs (on the market <5 yr) regardless of nature or severity
  - FDA Adverse Event Reporting System available for reporting

Variability in Drug Response

- recommended patient dosing is based on clinical research and represents mean values for a select population, but each person may be unique in their dosing requirements
- possible causes of individual variability in drug response include problems with:
  - intake: patient adherence
  - pharmacokinetics
    - absorption: vomiting, diarrhea or steatorrhea; first pass effect increased due to enzyme induction or decreased due to liver disease
    - drug interactions (e.g. calcium carbonate complexes with iron, thyroxine, and fluoroquinolones)
  - distribution: very high or low percentage body fat; intact or disrupted BBB; patient is elderly or a neonate, or has liver dysfunction
  - biotransformation and elimination: certain genetic polymorphisms or enzyme deficiencies related to drug metabolism (e.g. acetylcholinesterase deficiency, CYP polymorphism); kidney or liver dysfunction
  - pharmacodynamics: genetic variability in drug response (e.g. immune-mediated reactions); diseases that affect drug pharmacodynamics; drug tolerance or cross-tolerance

Drug Interactions

- concomitant prescriptions: one drug alters the effect of another by changing its PK and/or PD
- PK interactions involve
  - absorption: alterations in gastrointestinal pH, gastric emptying, intestinal motility, gut mucosal function
  - biotransformation: alterations in drug metabolizing enzymes
  - excretion: alterations in renal elimination
- PD interactions are due to two drugs that exert similar effects (additive) or opposing effects (subtractive)
- drug interactions can also involve herbal medications (e.g. St. John’s wort) and food (e.g. grapefruit)

Autonomic Pharmacology

</tbody>
</table>
the autonomic nervous system is divided into sympathetic and parasympathetic divisions
most organs are innervated by both sympathetic and parasympathetic nerves which have
opposing effects (see Neurology, N6)
• ACh and NE are the main neurotransmitters of the autonomic NS
• ACh binds to cholinergic receptors, which include nicotinic and muscarinic receptors
• NE binds to adrenergic receptors, which include β1, β2, α1, and α2
• ACh action is terminated by metabolism in the synaptic cleft by acetylcholinesterase and in the
plasma by pseudocholinesterase
  • acetylcholinesterase inhibitors (donepezil, galantamine, rivastigmine) are used to increase
ACh levels in conditions such as myasthenia gravis and Alzheimer’s disease
• NE action is terminated by reuptake by the presynaptic membrane, diffusion from the synaptic
cleft, and degradation by monoamine oxidase (MAO) and catechol-O-methyl transferase (COMT)

### Parasympathetic Nervous System

• blood vessels, sweat glands, spleen capsule, and adrenal medulla do NOT have parasympathetic
innervation
• parasympathetic pre-ganglionic fibers originate in the lower brainstem from cranial nerves III,
VII, IX, X, and in the sacral spinal cord at levels S2-S4 and connect with post-ganglionic fibers
via nicotinic receptors in ganglionic cells located near or within the target organ
• post-ganglionic fibers connect with effector tissues via:
  • M₁ muscarinic receptors located in the CNS
  • M₂ muscarinic receptors located in smooth muscle, cardiac muscle, and glandular
epithelium

### Sympathetic Nervous System

• sympathetic pre-ganglionic fibers originate in the spinal cord at spinal levels T1-L3
• pre-ganglionic fibers connect with post-ganglionic fibers via nicotinic receptors located in one
of two groups of ganglia
  1. paravertebral ganglia (i.e. the sympathetic trunk) that lie in a chain close to the vertebral
column
  2. pre-vertebral ganglia (i.e. celiac and mesenteric ganglia) that lie within the abdomen
• post ganglionic fibers connect with effector tissues via
  • β₁ receptors in cardiac tissue
  • β₂ receptors in smooth muscle of bronchi and GI tract
  • α₁ receptors in vascular smooth muscle
  • α₂ receptors in vascular smooth muscle
  • M₃ muscarinic receptors located in sweat glands

Introduction to Skin

Skin Anatomy

Skin

- divided anatomically into epidermis, dermis, and subcutaneous tissue
- **epidermis**
  - avascular: receives its nutrition from the dermal capillaries
  - derived from keratinocytes with the youngest presenting at the stratum basale
  - cells progress from stratum basale to stratum corneum in about 4 wk
  - stratum basale (germinativum): displays mitotic figures that give rise to keratinocytes
  - stratum spinosum (prickle cells): junctions in this layer (tonofilaments) give the epidermis its strength
  - stratum granulosum: flat cells containing basophilic granules which characterize skin
  - stratum lucidum: comprised of transparent layers of packed dead cells
  - stratum corneum: flat scales of the water-resistant protein keratin
- **dermis**: comprised of connective tissue divided into two regions
  - papillary: contains numerous capillaries that supply nutrients to the dermis and epidermis
  - reticular: provides a strong structure for skin; consists of collagen bundles woven together along with elastic fibers, fibroblasts, and macrophages
- **subcutaneous tissue** (subdermal)
  - consists primarily of adipose cells, larger caliber vessels, nerves and fascia

Cells in Epidermis

- keratinocytes: located in all layers of the epidermis, except the stratum corneum; connected to each other by desmosomes
- melanocytes: located in the stratum basale; keratinocyte to melanocyte ratio in the basal layer is 10:1; melanocyte number is equal among races
- Langerhans cells: important for immune surveillance
- Merkel cells: involved in touch sensation

Skin Appendages

- epidermal in origin, can extend into the dermis; includes hair, nails, and cutaneous glands

Cutaneous Glands

- **sebaceous gland**: part of pilosebaceous unit, produces sebum which is secreted into the hair follicle via the sebaceous duct, where it covers the skin surface (protective function)
- sebum has some antifungal properties
- these glands cover entire skin surface except palms and soles
- **apocrine sweat gland**: apocrine duct empties into hair follicle above sebaceous gland
  - found in axillae and perineum
  - likely a vestigial structure, functions in other species to produce scent (e.g. pheromones)
- **eccrine sweat gland**: not part of pilosebaceous unit
  - found over entire skin surface except lips, nail beds and glans penis
  - important in temperature regulation via secretion of sweat to cool skin surface

Figure 1. Histologic layers of the skin. Epidermal layer is detailed in A

Skin Function

- **protection**
  - due to continuous recycling and avascularity of epidermis
  - barrier to UV radiation, mechanical/chemical insults, pathogens and dehydration

- **thermal regulation**
  - insulation to maintain body temperature in cool environments via peripheral vasoconstriction, hair, and subcutaneous adipose tissue
  - dissipation of heat in warm environments via increased activity of sweat glands and increased blood flow within dermal vascular networks

- **sensation**
  - touch, pain, and temperature sensation

- **metabolic function**
  - vitamin D synthesis
  - energy storage (mainly in the form of triglycerides)

Definitions

**Primary Lesions**

**Definition**
- a lesion that the body makes that has not been altered by trauma or manipulation and has not regressed

**Types of Primary Lesions**

- **macule**: flat lesion, size less than 5 mm; differs from surrounding skin with respect to its color only
- **patch**: used by some dermatologists to mean a large macule, and others to mean a thin plaque
- **papule**: raised lesion less than 5 mm; its substance consists of inflammatory cells, neoplastic cells or accumulations of metabolic by-products e.g. lipids
- **plaque**: raised lesion; usually greater than 2 cm; its surface is greater than its height
- **nodule**: similar to a papule but measures 5 mm-5cm. Are often deep and palpable
- **tumor**: a large nodule; > 5 cm; tumor in this context does not imply malignancy
- **vesicle**: small raised lesion that is fluid-filled, <5 mm
- **bulla**: larger vesicle; >5 mm
- **pustule**: an elevated lesion containing purulent fluid (white, grey, yellow, green)

**Specific Types of Primary Lesions**

- **cyst**: an epithelial-lined collection containing semi-solid or fluid material
- **wheal**: a special form of papule or plaque that is blanchable and transient, formed by edema in the dermis (e.g. urticaria)
- **comedones**: collection of sebum and keratin
  - open comedo (blackhead)
  - closed comedo (whitehead; differentiated from pustule)
- **petechiae**: small pinpoint extravasation of blood into dermis resulting in hemorrhagic lesions; non-blanchable, <3 mm in size
- **purpura**: larger than petechia, 3 mm-1 cm in size
- **ecchymoses**: larger than purpura, >1 cm in size, i.e. a “bruise”
- **telangiectasia**: dilated superficial blood vessels; blanchable

**Secondary Morphological Lesions**

**Definition**
- develop during the evolutionary process of skin disease, or created by manipulation, or due to complication of primary lesion (e.g. rubbing, scratching, infection)
- **crust**: dried fluid (serum, blood, or purulent exudate) (e.g. impetigo)
- **scale**: excess keratin (e.g. seborrheic dermatitis)
- **lichenification**: thickening of the skin and accentuation of normal skin markings (e.g. chronic atopic dermatitis)
- **fissure**: a linear slit-like cleavage of the skin
- **excoriation**: a scratch mark
- **atrophy**: histological decrease in size and number of cells or tissues, resulting in thinning or depression of the skin

**Describe a Lesion with SCALDA**

**S**ize and **S**urface area

**C**olor (e.g. hyperpigmented, hypopigmented, erythematous)

**A**rrangement (e.g. solitary, linear, reticulated, grouped, herpetiform)

**L**esion morphology

**D**istribution (e.g. dermatomal, intertriginous, symmetrical/asymmetrical, follicular)

Always check hair, nails, mucous membranes and intertriginous areas

**Patch**: used by some dermatologists to mean a large macule, and others to mean a thin plaque

**Papule**: raised lesion less than 5 mm. Its substance consists of inflammatory cells, neoplastic cells or accumulations of metabolic by-products e.g. lipids
- **erosion**: a disruption of the skin involving the epidermis alone; heals without scarring
- **ulcer**: a disruption of the skin that extends into the dermis or deeper; heals with scarring
- **scar**: replacement fibrosis of dermis and subcutaneous tissue (hypertrophic or atrophic)

**Arrangement and Distribution**

- **acral**: relating to the hands and feet (e.g. hand, foot and mouth disease)
- **annular**: ring-shaped (e.g. granuloma annulare)
- **folicular**: involving hair follicles (e.g. folliculitis)
- **guttate**: lesions following a “drop-like” pattern (e.g. guttate psoriasis)
- **Koebner phenomenon**: i.e. isomorphic response, appearance of lesions at an injury site (e.g. lichen planus, psoriasis, vitiligo); an isomorphic reaction that develops in areas of trauma after the traumatic event; usually linear
- **morbiliform**: a maculopapular rash resembling measles
- **reticular**: lesions following a net-like pattern (e.g. livedo reticularis)
- **satellite**: lesions scattered outside of primary lesion (e.g. candida diaper dermatitis)
- **serpiginous**: lesions following a snake-like pattern (e.g. cutaneous larva migrans)
- **target/targetoid**: concentric ring lesions, like a dartboard (e.g. erythema multiforme). “Target” refers to lesions with 3 different zones of color and “targetoid” refers to lesions with 2 zones of color
- **other descriptive terms**: discrete, clustered, linear, confluent, , indurated
### Table 2. Cysts

<table>
<thead>
<tr>
<th>Clinical Presentation</th>
<th>Pathophysiology</th>
<th>Epidemiology</th>
<th>Clinical Course</th>
<th>Management</th>
</tr>
</thead>
<tbody>
<tr>
<td>Epidermal Cyst</td>
<td>Round, yellow/flesh-colored, slow growing, mobile, firm, fluctuant, red or tumor</td>
<td>Epithelial cells displaced into dermis, epidermal lining becomes filled with keratin and lipid-rich debris. May be post-traumatic, rarely syndromic</td>
<td>Most common cutaneous cyst in youth -- mid age</td>
<td>Central punctum may rupture (foul, cheesy odor, creamy color) and produce inflammatory reaction. Increase in size and number over time, especially in pregnancy. May become inflamed or infected.</td>
</tr>
<tr>
<td>Pilomotor Cyst</td>
<td>Single or multiple, hard, variable sized nodules under the scalp, lacks central punctum</td>
<td>Thick-walled cyst lined with stratified squamous epithelium and filled with dense keratin. Idiopathic</td>
<td>2nd most common cutaneous cyst F &gt; M</td>
<td>Rupture causes pain and inflammation.</td>
</tr>
<tr>
<td>Dermoid Cyst</td>
<td>Most commonly found at lateral third of eyebrow or midline under nose</td>
<td>Rare, congenital hamartomas, which arise from inclusion of epidermis along embryonal cleft closure lines, creating a thick-walled cyst filled with dense keratin.</td>
<td>Rare</td>
<td>If nasal midline, risk of extension into CNS.</td>
</tr>
<tr>
<td>Digital Mucous Cyst</td>
<td>Usually solitary, translucent; a clear gelatinous viscous fluid may be extruded</td>
<td>Cystic lesion that originates from joint or tendon sheath, called a digital mucous cyst when found on fingertip. Associated with osteoarthritis</td>
<td>Older age</td>
<td>Stable</td>
</tr>
<tr>
<td>Milium</td>
<td>1-2 mm superficial, white to yellow subepidermal papules occurring on eyelids, cheeks, and forehead</td>
<td>Small epidermal inclusion cyst, primarily arising from pluripotential cells in epidermal or adnexal epithelium.</td>
<td>Any age 40-50% of infants</td>
<td>In newborns, spontaneously resolves in first 4 wk of life</td>
</tr>
</tbody>
</table>
## Fibrous Lesions

### Dermatofibroma

**Clinical Presentation**
- button-like, firm dermal papule or nodule, skin-colored to red-brown coloring
- majority are asymptomatic but may be pruritic and/or tender
- site: legs > arms > trunk
- dimple sign: lateral compression causes dimpling of the lesion

**Pathophysiology**
- benign tumor due to fibroblast proliferation in the dermis

**Etiology**
- unknown; may be associated with history of minor trauma (e.g. shaving or insect bites)
- eruptive dermatofibromata can be associated with SLE

**Epidemiology**
- adults, F>M

**Differential Diagnosis**
- dermatofibrosarcoma protuberans, MM, Kaposi's sarcoma, blue nevus

**Investigations**
- biopsy if diagnosis is uncertain

**Management**
- no treatment required
- excision or cryosurgery if bothersome

---

### Skin Tags

**Clinical Presentation**
- small (1-10 mm), soft, skin-colored or darker pedunculated papule, often polypoid
- sites: eyelids, neck, axillae, inframammary, and groin

**Pathophysiology**
- benign outgrowth of skin

**Epidemiology**
- middle-aged and elderly, F>M, obese, can increase in size and number during pregnancy

**Differential Diagnosis**
- pedunculated seborrheic keratosis, compound or dermal melanocytic nevus, neurofibroma, fibroepithelioma of Pinkus (rare variant of BCC)

**Management**
- excision, electrodessication, cryosurgery

---

### Keloids

**Clinical Presentation**
- firm, shiny, skin-colored or red-bluish papules/nodules that most often arise from cutaneous injury (e.g. piercing, surgical scar, acne), but may appear spontaneously
- extends beyond the margins of the original injury, and may continue to expand in size for years with claw-like extensions
- can be pruritic and painful
- sites: earlobes, shoulders, sternum, scapular area

**Pathophysiology**
- excessive deposition of randomly organized collagen fibers following trauma to skin
- differentiated from a hypertrophic scar which is confined to the borders of the original injury

**Epidemiology**
- most common in black patients, followed by those of Asian descent (predilection for darker skin)
- M=F, all age groups

---

**Skin Tags are also known as**
- Acrochordons
- Fibroepithelial polyp
- Soft fibromas
- Pedunculated lipofibromas
- Cutaneous papillomas

---

**Keloids vs. Hypertrophic Scars**
- **Keloids**: extend beyond margins of original injury with claw-like extensions
- **Hypertrophic Scars**: confined to original margins of injury
Management
• intralesional corticosteroid injections
• cryotherapy
• silicone compression

Hyperkeratotic and Hyperplastic Lesions

SEBORRHEIC KERATOSIS

Clinical Presentation
• well-demarcated waxy papule/plaque with classic “stuck on” appearance
• large variety in color, size and shape
• over time lesions appear more warty, greasy and pigmented
• sites: face, trunk, upper extremities (may occur at any site except palms or soles)

Pathophysiology
• very common benign epithelial tumor

Epidemiology
• unusual <30 yr old
• autosomal dominant inheritance

Differential Diagnosis
• MM (lentigo maligna, nodular melanoma), melanocytic nevi, pigmented BCC, solar lentigo, spreading pigmented AK

Investigations
• biopsy only if diagnosis uncertain

Management
• none required, for cosmetics only
• cryotherapy, curettage

ACTINIC KERATOSIS (SOLAR KERATOSIS)
• see Pre-Malignant Skin Conditions, D31

KERATOACANTHOMA
• see Malignant Skin Tumors, D32

CORN

Clinical Presentation
• firm papule with a central, translucent, cone-shaped, hard keratin core
• painful with direct pressure
• sites: most commonly on dorsolateral fifth toe and dorsal aspects of other toes

Pathophysiology
• localized hyperkeratosis induced by pressure on hands and feet

Epidemiology
• F>M, can be caused by chronic microtrauma

Differential Diagnosis
• tinea pedis, plantar warts

Management
• relieve pressure with padding or alternate footwear, orthotics
• paring, curettage

Corns vs. Warts vs. Calluses
• Corns have a whitish yellow central translucent keratinous core; painful with direct pressure
• Warts bleed with paring and have a black speckled central appearance due to thrombosed capillaries; plantar warts destroy dermatoglyphics (epidermal ridges)
• Calluses have layers of yellowish keratin revealed with paring; there are no thrombosed capillaries or interruption of epidermal ridges
Pigmented Lesions and Pigmentary Disorders

Table 3. Comparison of Pigmented Lesions

<table>
<thead>
<tr>
<th>Type</th>
<th>Clinical Presentation</th>
<th>Pathophysiology</th>
<th>Epidemiology</th>
<th>Differential Diagnosis</th>
<th>Clinical Course and Management</th>
</tr>
</thead>
</table>
| Ephelides (Freckles)      | Small (<5 mm) well-demarcated light brown macules  
Sites: sun-exposed skin | Increased melanin within basal layer of keratinocytes secondary to sun exposure | Skin phototypes II-III | Junctional nevus  
Juvenile lentigines | No treatment required. Multiply and darken with sun exposure, fade in winter. Sunscreen may prevent the appearance of new freckles |
| Solar Lentigo (Liver Spot)| Well-demarcated brown/black irregular macules  
Sites: sun-exposed skin | Small increase in number of melanocytes in the basal layer and elongation of the rete ridges due to chronic sun exposure | Most common in Caucasians >40 yr  
Skin phototypes I-II | Lentigo maligna, seborrheic keratosis, pigmented solar keratitis | Laser therapy, shave excisions, cryotherapy |
| Dermal Melanocytosis      | Congenital gray-blue solitary or grouped macules commonly on lumbosacral area  
(historically known as Mongolian Spot) | Ectopic melanocytes in dermis | 99% occurs in Asian and Aboriginal infants | Ecchymosis | Usually fades in early childhood but may persist into adulthood |
| Becker’s Nevus            | Hairy, light brown macule/patch with a papular verrucous surface  
Sites: trunk and shoulders, onset in teen years | Pigmented hamartoma with increased melanin in basal cells | M>F  
Often becomes noticeable at puberty | Hairy congenital melanocytic nevus | Hair growth follows onset of pigmentary changes. Cosmetic management (usually too large to remove) |

NEVOMELANOCYTIC NEVI
- common mole  
- be suspicious of new or changing pigmented lesions (signs of melanoma)  
- average number of moles per person: 18-40 yr  
- 3 stages of evolution
  - junctional NMN: macular; arise at dermal-epidermal junction  
  - compound NMN: papular; nevus cells move into the papillary dermis  
  - dermal NMN: skin colored papules (no longer hyperpigmented); nevus cells completely migrate into dermis

Table 4. Nevomelanocytic Nevi Classification

<table>
<thead>
<tr>
<th>Type</th>
<th>Age of Onset</th>
<th>Clinical Presentation</th>
<th>Histology</th>
<th>Management</th>
</tr>
</thead>
<tbody>
<tr>
<td>Congenital</td>
<td>Birth and early infancy</td>
<td>Sharply demarcated pigmented brown plaque with regular/irregular contours and dermis (strands)</td>
<td>Nevomelanocytes in dermis (clusters) and dermis (strands)</td>
<td>Surgical excision if suspicious, due to increased risk of melanoma</td>
</tr>
</tbody>
</table>
| Acquired            | Early childhood to age 40  
Involutes by age 60 | Benign neoplasm of pigment-forming nevus cell  
Well circumscribed, round, uniformly pigmented macules/papules <1.5 cm  
Classified according to site of nevus cells | Excisional biopsy can be considered if on scalp, soles, mucous membranes, anogenital area, or if varied colors, irregular borders, pruritic, bleeding, exposed to trauma |
| Junctional          | Childhood  
Majority progress to compound nevus | Flat, irregularly bordered, uniformly tan-dark brown, sharply demarcated smooth macule | Melanocytes at dermal-epidermal junction above basement membrane | Same as above |
| Compound            | Any age  
Dermatomes, regularly bordered, smooth, round, tan-dark brown papule  
Sites: face, trunk, extremities, scalp | Melanocytes at dermal-epidermal junction; migration into dermis | Same as above |
| Dermal              | Adults  
Soft, dome-shaped, skin-colored tan/brown papules or nodules, often with telangiectasia  
Sites: face, neck | Melanocytes exclusively in dermis | Same as above |
| Atypical            | Childhood  
Variegated macule/papule/plaque  
May be large, may have regular borders or be asymmetric. May have a “fused-egg” appearance (central papule with surrounding macule)  
People with many atypical nevi and/or a family history of melanoma are at higher risk of developing a melanoma themselves | Hyperplasia and proliferation of melanocytes extending beyond dermal compartment of the nevus  
Often with region of adjacent nests | For patients with many atypical nevi, follow with full body photographs for changes. Excisional biopsy if lesion changing or highly atypical |

*Note: Junctional, compound and dermal nevi may be congenital or acquired. They may be typical or atypical.

DDx of Hyperpigmented Macules
- Purpura (e.g. solar, ASA, anti-coagulants, steroids, hemosiderin stain)  
- Post-inflammatory  
- Melasma  
- Melanoma  
- Fixed drug eruption
MELASMA

Clinical Presentation
- even tan macules on sun-exposed areas of face (forehead, upper lip, cheeks, chin)
- usually symmetrical

Pathophysiology
- increase in number and activity of melanocytes
- associated with estrogen and progesterone
- classification determined by depth of hyperpigmentation in the skin (epidermal, dermal, mixed type)
- epidermal pigmentation is most common and can be diagnosed with Wood’s light

Epidemiology
- F>>M
- common in pregnancy (chloasma = “mask of pregnancy”) and women taking OCP and HRT
- risk factors include sun exposure and dark skin tone
- can occur with mild endocrine disturbances, antiepileptic medications and other photosensitizing drugs

Management
- bleaching cream (hydroquinone), retinoic acid, topical steroids or combination creams
- destructive modalities (chemical peels, laser treatment)
- camouflage make-up
- avoiding sun and using sunscreen are key to preventing melasma
- often fades over several months after stopping hormone treatment or delivering baby

Vitiligo

Clinical Presentation
- primary pigmentary disorder characterized by depigmentation
- acquired destruction of melanocytes characterized by sharply marginated white patches
- associated with streaks of depigmented hair, chorioretinitis
- sites: extensor surfaces and periorificial areas (mouth, eyes, anus, genitalia)
- Koebner phenomenon, may be precipitated by trauma

Pathophysiology
- acquired autoimmune destruction of melanocytes

Epidemiology
- 1% incidence, polygenic
- 30% with positive family history

Investigations
- rule out associated autoimmune diseases: thyroid disease, pernicious anemia, Addison’s disease,
  Type I DM
- Wood’s lamp to detect lesions: illuminates UV light onto skin to detect amelanosis (porcelain white discoloration)

Management
- sun avoidance and protection
- topical calcineurin inhibitor (e.g. tacrolimus, pimecrolimus) or topical corticosteroids
- PUVA or Narrow band UVB
- make-up
- “bleaching” normal pigmented areas (i.e. monobenzyl ether of hydroquinone 20%) if widespread loss of pigmentation

HEMANGIOMAS

Clinical Presentation
- red or blue subcutaneous mass that is soft/compressible, blanches with pressure; feels like a “bag of worms” when palpated

Pathophysiology
- benign vascular tumor
- includes: infantile hemangioma, capillary/infantile hemangioma, spider hemangioma

Table 6. Vascular Tumors

<table>

</tbody>
</table>

VASCULAR MALFORMATIONS

1. Nevus Flammeus (Port-Wine Stain)

Clinical Presentation
- red to blue macule present at birth that follows a dermatomal distribution, rarely crosses midline
- most common site: nape of neck

Pathophysiology
- congenital vascular malformation of dermal capillaries; rarely associated with Sturge-Weber syndrome (V1, V2 distribution)

Management
- laser or make-up
2. Nevus Simplex (Salmon Patch)

Clinical Presentation
- pink-red irregular patches
- midline macule on glabella known as "Angel Kiss"; on nuchal region known as "Stork Bites"
- present in 1/3 of newborns
- majority regress spontaneously

Pathophysiology
- congenital dilation of dermal capillaries

Management
- no treatment required

Acneiform Eruptions

Acne Vulgaris/Common Acne

Clinical Presentation
- a common inflammatory pilosebaceous disease categorized with respect to severity
  - Type I: comedonal, sparse, no scarring
  - Type II: comedonal, papular, moderate ± little scarring
  - Type III: comedonal, papular, and pustular, with scarring
  - Type IV: nodulocystic acne, risk of severe scarring
- sites of predilection: face, neck, upper chest, and back

Pathophysiology
- hyperkeratinization, at the follicular ostia (opening), blocks the secretion of sebum
  (microcomedones)
- androgens stimulate sebaceous glands to produce sebum
- anaerobic diphtheroid Propionibacterium acnes bacteria contains lipase, which converts sebum
to free fatty acids and produces pro-inflammatory mediators

Epidemiology
- age of onset in puberty (10-17 yr in females, 14-19 yr in males)
- in prepubertal children consider underlying hormonal abnormality (e.g. late onset congenital
adrenal hyperplasia)
- more severe in males than in females
- incidence decreases in adulthood
- genetic predisposition: majority of individuals with cystic acne have parent(s) with history of
severe acne

Differential Diagnosis
- folliculitis, keratosis pilaris (upper arms, face, thighs), perioral dermatitis, rosacea

Table 7. Management of Acne

</tbody>
</table>

Acne Myths Debunked
- Eating greasy food and chocolate does not cause or worsen acne
- Blackheads (comedones) are black because of oxidized fatty acids, not dirt
- Acne is not caused by poor hygiene; on the contrary, excessive washing of face can be an aggravator

Acne Exacerbating Factors
- Systemic medications: lithium, phenytoin, steroids, halogens, androgens, iodides, bromides,
danazol, epidermal growth factor receptor inhibitors e.g. cetuximab
- Topical agents: steroids, tars, ointments, oily cosmetics
- Mechanical pressure or occlusion, such as leaning face on hands
- Emotional stress

Accutane and Pregnancy
- Use of isotretinoin during pregnancy is associated with spontaneous abortion and major birth defects such as facial dysmorphism and cognitive impairment
- Pregnancy should be ruled out before starting isotretinoin
- Ideally, patients should use 2 forms of contraception while on isotretinoin
- Patients and their health care providers need to register with iPledge (www.ipledge.com) before isotretinoin can be prescribed and comply with mandated procedure for use of this medication

Treatment of Acne Scars
- Tretinoin creams
- Microdermabrasion for superficial scars
- Injectable fillers (collagen, hyaluronic acid)
- Fraxel laser

Antibiotics are used in inflammatory skin conditions since they also have anti-inflammatory properties (e.g. macrolides in acne). Topical antibiotics may also be used to treat secondary bacterial superinfections (e.g. impetigo)

<td><strong>Tetracycline</strong></td>
<td>Inhibits protein synthesis</td>
<td>Use caution with regard to drug interactions: do not use with isotretinoin. Sun sensitivity</td>
</tr>
<tr>
<td><strong>Oral contraceptive pills (Ortho Tri-cyclen®, Estrostep® and Yas® are FDA-approved for acne treatment)</strong></td>
<td>Norgestimate, norethindrone, drospirenone: possesses anti-androgenic, progestogenic and antigonadotrophic activity</td>
<td>After 35 yr of age, estrogen/progesterone should only be considered in exceptional circumstances, carefully weighing the risk/benefit ratio with physician guidance</td>
</tr>
<tr>
<td><strong>Spironolactone (off-label use for acne)</strong></td>
<td>Ethinyl estradiol: increases level of SHBG, reducing circulating plasma levels of androgens</td>
<td>May cause hyperkalemia at higher doses</td>
</tr>
</tbody>
</table>

**SEVERE ACNE:** Consider systemic retinoids after above treatments have failed or if significant scarring present

<table>
<thead>
<tr>
<th>Drug Name</th>
<th>Mechanism of Action</th>
<th>Notes</th>
</tr>
</thead>
</table>
| **Isotretinoin (Accutane®, Claris®)** | Retinoid that inhibits sebaceous gland function and regulates keratinization | See Table 25, D44 for full side effect profile  
Most adverse effects are temporary and will resolve when the drug is discontinued  
Baseline lipid profile (risk of hypertriglyceridemia), LFTs and β-hCG before treatment  
May transiently exacerbate acne before patient sees improvement  
Drug may be discontinued at 16-20 wk when nodule count has dropped by >70%  
A second course may be initiated after 2 mo prn  
Refractory cases may require multiple courses of isotretinoin |

---

**Perioral Dermatitis**

**Clinical Presentation**
- discrete erythematous micropapules that often become confluent, forming inflammatory plaques on perioral, perinasal and periorbital skin
- commonly symmetrical, rim of sparing around vermilion border of lips

**Epidemiology**
- 15–40 yr old, occasionally in younger children
- predominantly females

**Differential Diagnosis**
- contact dermatitis, rosacea, acne vulgaris

**Management**
- avoid all topical steroids
- topical: metronidazole 0.75% gel or 0.75-1% cream to affected area bid

**Rosacea**

**Clinical Presentation**
- dome-shaped papules ± pustules
- flushing, non-transient erythema and telangiectasia
- distribution: typically on central face including forehead, nose, cheeks and chin; rarely on scalp, neck and upper body
- characterized by remissions and exacerbations
- exacerbating factors: heat, cold, wind, sun, stress, drinking hot liquids, alcohol, caffeine, spices
- all forms of rosacea can progress from mild to moderate to severe
- rarely in longstanding rosacea, signs of thickening, induration and lymphedema in the skin can develop
- phyma: a distinct swelling caused by lymphedema and hypertrophy of subcutaneous tissue, particularly affecting the nose (rhinophyma)
- ocular manifestations: blepharoconjunctivitis, keratitis, iritis

**Pathophysiology**
- unknown
Dermatitis (Eczema)

Definition
- inflammation of the skin

Clinical Presentation
- symptoms include pruritus and pain
- acute dermatitis: papules, vesicles
- subacute dermatitis: scaling, crusting
- chronic dermatitis: lichenification, xerosis, fissuring

Asteatotic Dermatitis

Clinical Presentation
- diffuse, mild pruritic dermatitis secondary to dry skin
- very common in elderly, especially in the winter (i.e. “winter itch”) but starts in the fall
- shins predominate, looks like a “dried river bed”

Management
- skin rehydration with moisturizing routine ± mild corticosteroid creams

Atopic Dermatitis

Clinical Presentation
- subacute and chronic eczematous reaction associated with prolonged severe pruritus
- distribution depends on age
- inflammation, lichenification, excoriation are secondary to relentless scratching
- atopic palms: hyperlinearity of the palms (associated with ichthyosis vulgaris)
- associated with: keratosis pilaris (hyperkeratosis of hair follicles, “chicken skin”), xerosis, occupational hand dryness

Epidemiology
- frequently affects infants, children, and young adults
- almost 15% of children in developed countries under the age of 5 are affected
- associated with personal or family history of atopy (asthma, hay fever, anaphylaxis, eosinophilia)
- polygenic inheritance: one parent >60% chance for child; two parents >80% chance for child
- the earlier the onset, the more severe and persistent the disease
- long-term condition with 1/3 of patients continuing to show signs of AD into adulthood

Pathophysiology
- a T-cell driven process with epidermal barrier dysfunction
Investigations
- clinical diagnosis
- consider: skin biopsy, immunoglobulin serum levels (often elevated serum IgE level), patch testing, and skin prick tests

Management
- goal: reduce signs and symptoms, prevent or reduce recurrences/flare
- better outcome (e.g. less flare-ups, modified course of disease) if diagnosis made early and treatment plan individualized
- avoid triggers of AD

- enhance barrier function of the skin
  - regular application of moisturizers
  - emollients hydrate the skin and reduce pruritus
  - twice daily application is recommended even in absence of symptoms, especially after bathing or swimming
  - bathing followed by the application of moisturizers and occlusives (e.g. petroleum jelly) promotes hydration

- anti-inflammatory therapies
  A. topical corticosteroids
    - effective, rapid symptomatic relief of acute flares
    - best applied immediately after bathing
    - control inflammation with a potent topical steroid; a milder one following resolution of acute flare
    - systemic immunosuppression may be needed in severe cases
    - flares may respond to systemic anti-staphylococcal therapy
    - side effects: skin atrophy, purpura, striae, steroid acne, perioral dermatitis, and glaucoma when used around the eyes
  B. topical immunomodulators
    - long-term management
    - calcineurin inhibitors include pimecrolimus (Elidel®), tacrolimus (Protopic®)
    - side effects: skin burning, transient irritation
    - advantages of immunomodulators over long-term corticosteroid use: rapid, sustained effect in controlling pruritus; no skin atrophy; safe for the face and neck

Complications
- infections
  - treatment of infections
    - topical mupirocin
    - oral antibiotics (e.g. cloxacillin, cephalixin) for widespread S. aureus infections

Figure 5. Atopic dermatitis treatment algorithm

Clin Dermatol 2010;28:36-44

Study: Systematic review.

Conclusions
Use of the atopy patch test (APT) is controversial:
- There is no gold standard for allergen provocation, so APT is used without comparison to another method.
- APT findings are not consistent among children with atopic dermatitis.

APT may be valuable:
- May provide diagnostic information and may aid clinical decision making regarding the use of IgE-mediated sensitizations.

Future research is needed:
- Need standardized provocation and avoidance testing to determine the clinical relevance of obtaining a positive APT result.
Contact Dermatitis

Clinical Presentation
- cutaneous inflammation caused by an external agent(s)

</tbody>
</table>

Dyshidrotic Dermatitis

Clinical Presentation
- “tapioca pudding” papulovesicular dermatitis of hands and feet that coalesce into plaques, followed by painful fissuring
- acute stage often very pruritic
- secondary infection common
- lesions heal with desquamation and may lead to chronic lichenification
- sites: palms and soles ± dorsal surfaces of hands and feet

Pathophysiology
- NOT caused by hyperhidrosis (excessive sweating)
- emotional stress may precipitate the dermatitis

Management
- topical: high potency corticosteroid with plastic cling wrap occlusion to increase penetration
- intralesional triamcinolone injection
- systemic
  - prednisone in severe cases
  - antibiotics for secondary S. aureus infection

Nummular Dermatitis

Clinical Presentation
- annular, coin-shaped, pruritic, dry, scaly, erythematous plaques, can become lichenified
- often associated with atopic and dyshidrotic dermatitis
- secondary infection common

Pathophysiology
- little is known, but it is often accompanied by xerosis, which results from a dysfunction of the epidermal lipid barrier; this in turn can allow permeation of environmental agents, which can induce an allergic or irritant response

Management
- moisturization
- mid to high potency corticosteroid ointment bid
**Seborrheic Dermatitis**

**Clinical Presentation**
- greasy, erythematous, yellow, scaling, minimally elevated papules and plaques in areas rich in sebaceous glands, can look moist and superficially eroded in flexural regions
- infants: "cradle cap"
- children: may be generalized with flexural and scalp involvement
- adults: diffuse involvement of scalp margin with yellow to white flakes, pruritus, and underlying erythema
- sites: scalp, eyebrows, eyelashes, beard, glabella, post-auricular, over sternum, trunk, body folds, genitalia

**Pathophysiology**
- possible etiologic association with *Malassezia* spp. (yeast)

**Epidemiology**
- common in infants and adolescents
- increased incidence and severity in immunocompromised patients
- in adults, can cause dandruff ( pityriasis sicca)

**Management**
- face: ketoconazole (Nizoral®) cream daily or bid + mild steroid cream daily or bid
- scalp: salicylic acid in olive oil or Derma-Smoothe FS® oil (peanut oil, mineral oil, fluocinolone acetonide 0.01%) to remove dense scales, 2% ketoconazole shampoo (Nizoral®), ciclopirox (Loprox®) shampoo, selenium sulfide (e.g. Selsun®) or zinc pyrithione (e.g. Head and Shoulders®) shampoo, steroid lotion (e.g. betamethasone valerate 0.1% lotion bid)

**Stasis Dermatitis**

**Clinical Presentation**
- chronic erythema, xerosis, scaling, pruritis, and brownish pigmentation in late stages
- site: lower legs

**Pathophysiology**
- chronic venous insufficiency leads to venous stasis
- surrounding soft tissue inflammation and fibrosis results

**Investigations**
- Doppler and color-coded Duplex sonography if suspicious for DVT
- culture for MRSA if there is crusting

**Management**
- compression stockings
- rest and elevate legs (above the level of the heart)
- moisturizer to treat xerosis
- mid-high potency topical corticosteroids to control inflammation

**Complications**
- ulceration (common at medial malleolus), secondary bacterial infections

**Lichen Simplex Chronicus**

**Clinical Presentation**
- well-defined plaque(s) of lichenified skin with decreased skin markings ± excoriations
- common sites: neck, scalp, lower extremeties, urogenital area
- often seen in patients with atopy

**Pathophysiology**
- skin hyperexcitable to itch, continued rubbing/scratching of skin results
- eventually lichenification occurs

**Investigations**
- if patient has generalized pruritus, rule out systemic cause: CBC with differential count, transaminases, renal and thyroid function tests
- CXR if lymphoma suspected

**Management**
- treat pruritus to break the itch-scratch cycle: antipruritics (e. g. antihistamines, topical or intralesional glucocorticoids, Unna boot)
**Lichen Planus**

**Clinical Presentation**
- acute or chronic inflammation of mucous membranes or skin, especially on flexural surfaces
- small, polygonal, pruritic, flat-topped, shiny, violet papules; resolves into hyperpigmented macules
- common sites: wrists, ankles, mucous membranes in 60% (mouth, vulva, glans), nails, scalp
- distribution: symmetrical and bilateral
- Wickham's striae: reticulate white-gray lines over surface; pathognomonic but may not be present
- mucous membrane lesions: lacy, whitish reticular network, milky-white plaques/papules; increased risk of SCC in erosions and ulcers
- nails: longitudinal ridging; dystrophic; pterygium formation
- scalp: scarring alopecia with perifollicular hyperkeratosis
- spontaneously resolves but may last for weeks, months or years (mouth and skin lesions)
- rarely associated with hepatitis C
- Koebner phenomenon

**Pathophysiology**
- autoimmune, antigen unknown
- lymphocyte activation leads to keratinocyte apoptosis

**Investigations**
- biopsy
- hepatitis C serology if patient has risk factors

**Management**
- topical or intralesional corticosteroids
- short courses of oral prednisone (rarely)
- phototherapy for generalized or resistant cases
- oral retinoids for erosive lichen planus in mouth
- oral metronidazole or systemic immunosuppressants (e.g. azathioprine, methotrexate, cyclosporine)

---

**Pityriasis Rosea**

**Clinical Presentation**
- acute, self-limiting eruption characterized by red, oval plaques/patches with central scale that does not extend to edge of lesion
- long axis of lesions follows skin tension lines (i.e. Langer's Lines) parallel to ribs producing "Christmas tree" pattern on back
- varied degree of pruritus
- most start with a "herald" patch which precedes other lesions by 1-2 wk
- common sites: trunk, proximal aspects of arms and legs

**Etiology**
- suspected HHV-7 or HHV-6 reactivation

**Investigations**
- none required

**Management**
- none required; clears spontaneously in 6-12 wk
- symptomatic: topical glucocorticoids if pruritic

---

**Psoriasis**

**Classification**
1. plaque psoriasis
2. guttate psoriasis
3. erythrodermic psoriasis
4. pustular psoriasis
5. inverse psoriasis

**Pathophysiology**
- not fully understood, genetic and immunologic factors
- shortened keratinocyte cell cycle leads to Th1- and Th17-mediated inflammatory response
- Physical trauma (Koebner phenomenon)
- Infections (acute streptococcal infection precipitates guttate psoriasis)
- Stress (can be a major factor in flares)
- Drugs (rebond from stopping systemic glucocorticoids, lithium, antimalarial drugs, interferon)
- Smoking and heavy alcohol consumption
Differential Diagnosis
- AD, mycosis fungoides (cutaneous T-cell lymphoma), seborrheic dermatitis, tinea, nummular dermatitis, lichen planus

Investigations
- biopsy (if atypical presentation, rarely needed)

1. PLAQUE PSORIASIS

Clinical Presentation
- chronic and recurrent disease characterized by well-circumscribed erythematous papules/plaques with silvery-white scales
- often worse in winter (lack of sun and humidity)
- Auspitz sign: bleeds from minute points when scale is removed
- common sites: scalp, extensor surfaces of elbows and knees, trunk (especially buttocks), nails, pressure areas

Management

*Can also be used to treat psoriatic arthritis

- biologics under study for treatment of psoriasis: secukinumab, brodalumab, ixekizumab, tildrakizumab, guselkumab

2. GUTTATE PSORIASIS (“DROP-LIKE”)

Clinical Presentation
- discrete, scattered salmon-pink small scaling papules
- sites: diffuse, usually on trunk and legs, sparing palms and soles
- often antecedent streptococcal pharyngitis
Management
- UVB phototherapy, sunlight, lubricants
- penicillin V or erythromycin if Group A β-hemolytic Streptococcus on throat culture

3. ERYTHRODERMIC PSORIASIS

Clinical Presentation
- generalized erythema with fine desquamative scale on surface
- associated signs and symptoms: arthralgia, severe pruritus, dehydration, electrolyte imbalance
- may have history of mild plaque psoriasis
- aggravating factors: lithium, β-blockers, NSAIDs, antimalarials, phototoxic reaction, infection

Management
- hospitalization, bed rest, IV fluids, monitor fluids and electrolytes
- treat underlying aggravating condition, sun avoidance
- methotrexate, cyclosporine, UV, oral retinoids, biologics

4. PUSTULAR PSORIASIS

Clinical Presentation
- sudden onset of erythematous macules and papules which evolve rapidly into pustules, very painful
- can be generalized or localized to palms/soles
- patient usually has history of psoriasis; may occur with sudden withdrawal from steroid therapy

Management
- methotrexate, cyclosporine, oral retinoids, biologics
- hospitalization if generalized

5. INVERSE PSORIASIS

Clinical Presentation
- erythematous well-demarcated plaques on flexural surfaces such as axillae, inframammary folds, gluteal fold, inguinal folds
- lesions may be macerated

Management
- low potency topical corticosteroids
- topical vitamin D derivatives such as calcipotriene or calcitriol
- topical calcineurin inhibitors such as tacrolimus or pimecrolimus

6. PSORIATIC ARTHRITIS
- 5-30% of patients with psoriasis can also be suffering from psoriatic arthritis
- psoriatic patients with nail or scalp involvement are at a higher risk for developing psoriatic arthritis
- see Rheumatology, RH23

Vesicobullous Diseases

Bullous Pemphigoid

Clinical Presentation
- chronic autoimmune bullous eruption characterized by pruritic, tense, subepidermal bullae on an erythematous or normal skin base
- sometimes presents as urticarial plaques without bullae
- common sites: flexor aspect of forearms, axillae, medial thighs, groin, abdomen, mouth in 33%

Pathophysiology
- IgG produced against dermal-epidermal basement membrane proteins (hemidesmosomes) leads to subepidermal bullae

Epidemiology
- mean age of onset: 60-80 yr old
- possible rare association with internal malignancy
Dermatitis Herpetiformis

Clinical Presentation
- Grouped papules/vesicles/urticarial wheals on an erythematous base, associated with intense pruritus, burning, stinging, excoriations
- Lesions grouped, bilaterally symmetrical
- Common sites: extensor surfaces of elbows/knees, sacrum, buttocks, scalp

Pathophysiology
- Transglutaminase IgA deposits in the skin alone or in immune complexes leading to eosinophil and neutrophil infiltration
- 90% have HLA B8, DR3, DQWZ
- 90-100% associated with an often subclinical gluten-sensitive enteropathy (i.e. celiac disease)
- 30% have thyroid disease; increased risk of intestinal lymphoma in untreated comorbid celiac disease; iron/folate deficiency is common

Investigations
- Biopsy
- Immunofluorescence shows IgA deposits in perilesional skin

Epidemiology
- 20-60 yr old, M:F = 2:1

Pemphigus Foliaceus

An autoimmune intraepidermal blistering disease that is more superficial than pemphigus vulgaris due to antibodies against desmoglein-1, a transmembrane adhesion molecule. Appears as crusted patches, erosions and/or flaccid bullae that usually start on the trunk. Localized disease can be managed with topical steroids. Active widespread disease is treated like pemphigus vulgaris.

Pemphigus Vulgaris

Clinical Presentation
- Autoimmune blistering disease characterized by flaccid, non-pruritic intraepidermal bullae/vesicles on an erythematous or normal skin base
- May present with erosions and secondary bacterial infection
- Sites: mouth (90%), scalp, face, chest, axillae, groin, umbilicus
- Nikolsky’s sign: Rubbing pressure on skin to cause bulla formation
- Asboe-Hansen sign: Pressure applied to bulla causes it to extend laterally

Pathophysiology
- IgG against epidermal desmoglein-1 and -3 leads to intraepidermal bullae

Epidemiology
- 40-60 yr old, higher prevalence in Jewish, Mediterranean, Asian populations
- Paraneoplastic pemphigus may be associated with thymoma, myasthenia gravis, malignancy, and use of D-penicillamine

Investigations
- Immunofluorescence: shows IgG and C3 deposition intraepidermally
- Circulating serum anti-desmoglein IgG antibodies

Prognosis
- Begins with mouth lesions, followed by skin lesions
- Lesions heal with hyperpigmentation but do not scar
- May be fatal unless treated with immunosuppressive agents

Management
- Prednisone 1-2 mg/kg until no new blisters, then 1-1.5 mg/kg until clear, then taper ± steroid-sparing agents (e.g. azathioprine, methotrexate, gold, cyclophosphamide, cyclosporine, IVlg, mycophenolate mofetil, rituximab)
Management
• dapsone for pruritus (sulfapyridine if contraindicated or poorly tolerated)
• gluten-free diet for life

**Porphyria Cutanea Tarda**

**Clinical Presentation**
• tense vesicles/bullae in photoexposed areas subjected to trauma
• facial hypertrichosis, vesicles, and bullae in photodistribution (dorsum of hands and feet), milia, scarring
• common sites: light-exposed areas subjected to trauma, dorsum of hands and feet, nose, and upper trunk

**Pathophysiology**
• autosomal dominant or sporadic skin disorder associated with the presence of excess heme precursors
• associated with hemochromatosis, alcohol abuse, DM, drugs (estrogen therapy, NSAIDs), HIV, hepatitis C, increased iron indices

**Epidemiology**
• 30-40 yr old, M>F

**Investigations**
• urine + 5% HCl shows orange-red fluorescence under Wood's lamp (UV rays)
• 24 h urine for uroporphyrins (elevated)
• stool contains elevated coproporphyrins
• immunofluorescence shows IgE at dermal-epidermal junctions

**Management**
• discontinue aggravating substances (alcohol, estrogen therapy)
• phlebotomy to decrease body iron load
• low dose hydroxychloroquine

**Drug Eruptions**

**Drug Hypersensitivity Syndrome**
• fever followed by symmetrical bright red exanthematous eruption that may lead to internal organ involvement (e.g. hepatitis, arthralgia, nephritis, pneumonitis, lymphadenopathy, hematologic abnormalities, thyroid abnormalities)
• classically occurs approximately 7-10 d after first exposure to the drug
• may be elevated incidence of similar reactions in siblings
• most common causes: sulfonamides, allopurinol, and anticonvulsants (e.g. phenytoin, phenobarbital, carbamazepine, lamotrigine)
• 10% mortality if severe, undiagnosed, and untreated
• management: discontinue offending drug ± prednisone 0.5 mg-1 mg/kg/d, consider cyclosporine or other steroid-sparing agent in severe cases

**Erythema Multiforme, Stevens-Johnson Syndrome, Toxic Epidermal Necrolysis**
• disorders with varying presence of characteristic skin lesions, blistering and mucous membrane involvement
Table 13. Comparison of Erythema Multiforme, Stevens-Johnson Syndrome, Toxic Epidermal Necrolysis

</tbody>
</table>

* SJS/TEN overlap is defined as the presence of 10-30% detached and detachable skin

Exanthematous Eruptions (Maculopapular Eruptions/Morbilliform)

- symmetrical, widespread, erythematous patches or plaques ± scales
- the “classic” and most common adverse drug reaction
- often starts on trunk
- may progress to generalized exfoliative dermatitis especially if the drug is continued
- most common causes: penicillin, sulfonamides, phenytoin
- management: discontinue offending drug ± oral antihistamines or topical/oral corticosteroids

Fixed Drug Eruptions

- sharply demarcated erythematous oval patches on the skin or mucous membranes
  - common sites: face, mucosa, genitalia, acral
  - recurs in same location upon subsequent exposure to the drug (fixed location)
- most common causes: antimicrobials (tetracycline, sulfonamides), anti-inflammatories, psychoactive agents (barbiturates), phenolphthalein
- management: discontinue offending drug ± prednisone 1mg/kg/d x 2 wk for generalized lesions ± potent topical corticosteroids for non-eroded lesions or antimicrobial ointment for eroded lesions

Photosensitivity Eruptions

- phototoxic reaction: “an exaggerated sunburn” confined to sun-exposed areas
- photoallergic reaction: an eczematous eruption that may spread to areas not exposed to light
- most common causes: chlorpromazine, doxycycline, thiazide diuretics, procarbazine
- management: sun protection ± topical/oral corticosteroids

Intravenous Immunoglobulin Use in Patients with Toxic Epidermal Necrolysis and Stevens-Johnson Syndrome

Am J Clin Dermatol 2006;7:359-368

Study: Systematic review of 17 articles (retrospective cohort studies were most common, no RCTs).

Patients: Individuals with a diagnosis of SJS/TEN treated with IVIg.

Intervention: Various doses and regimens of IVIg.

Outcomes: Time to disease cessation, time to healing.

Results: Eleven of 14 TEN studies reported positive results, while three studies did not observe a statistically significant improvement. Two of three SJS studies reported positive results, with one study observing no significant difference in mortality, or speed of healing.

Conclusion: IVIg appears to have a positive impact on TEN/SJS but results cannot be statistically analyzed as a whole due to variability and inconsistency in data presented from each study. However, it is considered the gold standard treatment.
**Serum Sickness-Like Reaction**

- a symmetric drug eruption resulting in fever, arthralgia, lymphadenopathy, and skin rash (urticaria)
- usually appears 5-10 d after drug exposure
- most common causes: cefaclor in kids; bupropion (Zyban®, Wellbutrin®) in adults
- management: discontinue offending drug ± topical/oral corticosteroids

**Heritable Disorders**

**Ichthyosis Vulgaris**

**Clinical Presentation**
- generalized hyperkeratosis leading to dry skin
- “fish-scale” appearance especially on extremities with sparing of flexural creases, palms and soles

**Pathophysiology**
- genetic deficiency in filaggrin protein leads to abnormal retention of keratinocytes (hyperkeratosis)
- scaling without inflammation

**Epidemiology**
- 1:300 incidence
- autosomal dominant inheritance
- associated with AD and keratosis pilaris

**Investigations**
- electron microscopy: keratohyalin granules

**Management**
- immersion in bath and oils followed by an emollient cream, humectant cream, or creams/oil containing urea or α- or β-hydroxy acids
- intermittent systemic retinoids for severe cases

**Neurofibromatosis (Type I; von Recklinghausen’s Disease)**

**Clinical Presentation**
- diagnostic criteria includes 2 or more of the following
  1. more than 5 café-au-lait patches >1.5 cm in an adult or more than 5 café-au-lait macules >0.5 cm in a child under age 5 yr
  2. axillary or inguinal freckling
  3. iris hamartomas (Lisch nodules)
  4. optic gliomas
  5. neurofibromas
  6. distinctive bony lesion (sphenoid wing dysplasia or thinning of long bone cortex)
- associated with pheochromocytoma, astrocytoma, bilateral acoustic neuromas, bone cysts, scoliosis, precocious puberty, developmental delay, and renal artery stenosis
- skin lesions less prominent in neurofibromatosis Type II (see Pediatrics, P88)

**Pathophysiology**
- autosomal dominant disorder with excessive and abnormal proliferation of neural crest elements (Schwann cells, melanocytes), high incidence of spontaneous mutation
- linked to absence/truncation of neurofibromin (a tumour suppressor gene)

**Epidemiology**
- incidence 1:3,000

**Investigations**
- Wood’s lamp examination to detect café-au-lait macules in patients with pale skin

**Management**
- refer to orthopedics, ophthalmology, plastics, and psychology for relevant management
- follow-up annually for brain tumors such as astrocytoma
- excise suspicious or painful lesions
- see Pediatrics, P88
**Epidemic Infections**

**Impetigo**

**Clinical Presentation**
- Acute purulent infection which appears micro-pustular; progresses to golden yellow “honey-crusted” lesions surrounded by erythema
- Can present with bullae
- Common sites: face, arms, legs, and buttocks

**Etiology**
- GAS, *S. aureus*, or both

**Epidemiology**
- Preschool and young adults living in crowded conditions, poor hygiene, neglected minor trauma

**Differential Diagnosis**
- Infected eczema, HSV, VZV

**Investigations**
- Gram stain and culture of lesion fluid or biopsy

**Management**
- Remove crusts, use saline compresses and topical antiseptic soaks bid
- Topical antibacterials such as 2% mupirocin or fusidic acid (Canada only) tid; continue for 7-10 d after resolution
- Systemic antibiotics such as cloxacillin or cephalaxin for 7-10 d

**Dermis**

Dermatophytoses

Clinical Presentation
- infection of skin, hair and nails caused by dermatophytes (fungi that live within the epidermal keratin or hair follicle and do not penetrate into deeper structures)

Pathophysiology
- digestion of keratin by dermatophytes results in scaly skin, broken hairs, crumbling nails/onycholysis

Etiology
- *Trichophyton, Microsporum, Epidermophyton* species (*Pityrosporum* is a superficial yeast and not a dermatophyte)

Investigations
- skin scrapings, hair, and/or nail clippings analyzed with potassium hydroxide (KOH) prep to look for hyphae and mycelia Nails can also be sent to pathology for PAS staining

Management
- topicals as first line agents for tinea corporis/cruris and tinea pedis (interdigital type): clotrimazole, or terbinafine or ciclopirox olamine cream applied bid
- oral therapy is often indicated for onychomycosis or tinea capitis although ciclopirox nail lacquer bid x 6 mo is an option in those unable to take oral:
  - e.g. terbinafine (Lamisil® – liver toxicity, CYP2D6 inhibitor) or itraconazole (Sporanox® – CYP3A4 inhibitor, liver toxicity, CHF)

</tr>
</tbody>
</table>

### Parasitic Infections

**SCABIES**

**Clinical Presentation**
- characterized by superficial burrows, intense pruritus (especially nocturnal), and secondary infection
- primary lesion: superficial linear burrows; inflammatory papules and nodules. Most common sites: finger webs, periungual and groin
- secondary lesion: small crusted papules, eczematous plaques, excoriations
- common sites: axillae, groin, buttocks, hands/feet (especially web spaces), sparing of head and neck (except in infants)

**Pathophysiology**
- scabies mite remains alive 2-3 d on clothing/sheets, however eggs can take 7 days to hatch
- incubation of 1 mo, then pruritus begins
- re-infection followed by hypersensitivity in 24 h

**Etiology**
- *Sarcoptes scabiei* (a mite)
- risk factors: sexual promiscuity, crowding, poverty, nosocomial, immunocompromised

**Differential Diagnosis**
- asteatotic eczema, dermatitis herpetiformis, lichen simplex chronicus (neurodermatitis)

**Investigations**
- microscopic examination of root and content of burrow and mineral oil mount for mite, eggs, feces
- skin biopsy may sometimes show scabies mite

**Management**
- bathe, then apply permethrin 5% cream (i.e. Nix®) from neck down to soles of feet (must be left on for 8-14 h and requires second treatment as it is not ovicidal)
- in pregnancy permethrin is not used due to neurotoxicity. Instead topical sulfur is considered safe
- change underwear and linens; wash twice with detergent in hot water cycle then machine dry
- treat family and close contacts
- pruritus may persist for 2 months after effective treatment due to prolonged hypersensitivity reaction
- mid potency topical steroids and antihistamines for symptom management
LICE (PEDICULOSIS)

Clinical Presentation
- intensely pruritic red excoriations, morbilliform rash, caused by louse (a parasite)
- scalp lice: nits (i.e. louse eggs) on hairs; red, excoriated skin with secondary bacterial infection, lymphadenopathy
- pubic lice: nits on hairs; excoriations
- body lice: nits and lice in seams of clothing; excoriations and secondary infection mainly on shoulders, belt-line and buttocks

Etiology
- Phthirius pubis (pubic), Pediculus humanus capitis (scalp), Pediculus humanus humanus (body): attaches to body hair and feeds
- can transmit infectious agents such as Bartonella quintana and Rickettsia prowazekii

Differential Diagnosis
- on scalp: bacterial infection of scalp, seborrheic dermatitis, on body: scabies

Diagnosis
- lice visible on inspection of affected area or clothing seams

Management
- permethrin 1% (Nix® cream rinse) (ovicidal) or permethrin 1% (RC & Cor®, Kwellada-P® shampoo)
- comb hair with fine-toothed comb using dilute vinegar solution to remove nits
- repeat in 7 d after first treatment
- shave hair if feasible, change clothing and linens; wash with detergent in hot water cycle then machine dry
- treat sexual contacts in case of pubic lice

BED BUGS (HEMIPTERA)

Clinical Presentation
- burning wheals, turning to firm papules, often in groups of three – “breakfast, lunch and dinner” – in areas with easy access (face, neck, arms, legs, hands)

Etiology
- caused by Cimex lectularius, a small insect that feeds mainly at night (hide in crevices in walls and furniture during the day)

Differential Diagnosis
- dermatitis herpetiformis, drug eruptions, eczema, other insect bites, scabies

Investigations
- none required, but lesional biopsy can confirm insect bite reaction

Management
- professional fumigation
- topical steroids and oral H1-antagonists for symptomatic relief
- definitive treatment is removal of clutter in home and application of insecticides to walls and furniture

Viral Infections

HERPES SIMPLEX

Clinical Presentation
- herpetiform (i.e. grouped) vesicles on an erythematous base on skin or mucous membranes
- transmitted via contact with erupted vesicles or via asymptomatic viral shedding
- primary
  - children and young adults
  - usually asymptomatic; may have high fever, regional lymphadenopathy, malaise
  - followed by antibody formation and latency of virus in dorsal nerve root ganglion
- secondary
  - recurrent form seen in adults; much more common than primary
  - prodrome: tingling, pruritus, pain
  - triggers for recurrence: fever, excess sun exposure, physical trauma, menstruation, emotional stress, URTI
- potential complications
  - dendritic corneal ulcer
  - Erythema Multiforme
  - herpes simplex encephalitis (infants at risk)
HSV infection on atopic dermatitis causing Kaposi's varicelliform eruption (eczema herpeticum)
- two biologically and immunologically different subtypes: HSV-1 and HSV-2

**Investigations**
- Tzanck smear with Giemsa stain shows multinucleated giant epithelial cells most common investigation although diagnosis is usually clinical
- viral culture, electron microscopy, and direct fluorecence antibody test of specimen taken from the base of a relatively new lesion
- serologic testing for antibody for current or past infection if necessary rarely performed as expensive, and high prevalence of positives

**HSV-1**
- typically “cold sores” (grouped vesicles at the mucocutaneous junction which quickly burst)
- recurrent on face, lips and hard palate, but NOT on soft, non-keratinized mucous membranes (unlike aphthous ulcers)

**Management**
- treat during prodrome to prevent vesicle formation
- topical antiviral (Zovirax®) cream, apply 5-6x/d x 4-7 d for facial/genital lesions
- oral antivirals (e.g. acyclovir, famciclovir, valacyclovir) are far more effective and have an easier dosing schedule, can be used at first sign of prodrome or if frequent outbreaks as prophylactic suppression

**HSV-2**
- sexually transmitted; incubation 2-20 d
- gingivostomatitis: entire buccal mucosa involved with erythema and edema of gingiva
- vulvovaginitis: edematous, erythematous, extremely tender, profuse vaginal discharge
- urethritis: watery discharge in males
- recurrent on vulva, vagina, penis for 5-7 d
- dx of genital ulcers: Candida balanitis, chancroid, syphilitic chancre

**Management**
- rupture vesicle with sterile needle if you wish to culture it
- wet dressing with aluminum subacetate solution, Burow’s compression, or betadine solution
- 1st episode: acyclovir 200 mg PO 5 times a day x 10 d
  - maintenance: acyclovir 400 mg PO bid
  - famciclovir or valacyclovir may be substituted and have better enteric absorption and less frequent dosing
- in case of herpes genitalis, look for and treat any other sexually-transmitted infections
- for active lesions in pregnancy, see Obstetrics, OB20

**HERPES ZOSTER (SHINGLES)**

**Clinical Presentation**
- unilateral dermatomal eruption occurring 3-5 d after pain and paresthesia of that dermatome; may be disseminated in Immunosuppressed (eg HIV, organ transplant)
- vesicles, bullae, and pustules on an erythematous, edematous base
- lesions may become eroded/ulcerated and last days to weeks
- pain is can be pre-herpetic, synchronous with rash, or post-herpetic
- severe post-herpetic neuralgia often occurs in elderly and may be permanent
- Hutchinson's sign: involvement of tip of nose suggests eye involvement
- distribution: thoracic (50%), trigeminal (10-20%), cervical (10-20%); disseminated in HIV

**Etiology**
- caused by reactivation of VZV
- risk factors: immunosuppression, old age, occasionally associated with hematologic malignancy, stress

**Differential Diagnosis**
- before thoracic skin lesions occur, must consider other causes of chest pain
- contact dermatitis, localized bacterial infection, zosteriform HSV (more pathogenic for the eyes than VZV)

**Investigations**
- none required, but can do Tzanck test, direct fluorescence antibody test, or viral culture to rule out HSV

**Management**
- compress with normal saline, Burow's, or betadine solution
- analgesics (NSAIDs, amitriptyline)
- famciclovir or valacyclovir or acyclovir for 7 d; must initiate within 72 h to be of benefit; IV acyclovir for ophthalmic or disseminated Involvement
- gabapentin 300-600 mg PO tid for post-herpetic neuralgia
MOLLUSCUM CONTAGIOSUM

Clinical Presentation
- discrete dome-shaped and umbilicated pearly, white papules caused by DNA Pox virus (Molluscum contagiosum virus); giant verrucous forms in advanced HIV
- common sites: eyelids, beard (likely spread by shaving), neck, axillae, trunk, perineum, buttocks

Etiology
- virus is spread via direct contact, auto-inoculation, sexual contact
- common in children and sexually active young adults (giant molluscum and severe cases can be seen in the setting of HIV)

Investigations
- none required, however can biopsy to confirm diagnosis

Management
- topical cantharidin (a vesicant)
- cryotherapy
- curettage
- topical retinoids
- Aldara® (imiquimod): immune modulator that produces a cytokine inflammation

WARTS (VERRUCA VULGARIS) (HUMAN PAPILLOMAVIRUS INFECTIONS)

Table 17. Different Manifestations of HPV Infection

<table>
<thead>
<tr>
<th>Verruca Vulgaris (Common Warts)</th>
<th>Verruca Plantaris (Plantar Warts) and Verruca Palmaris (Palmar Warts)</th>
<th>Verruca Planae (Flat Warts)</th>
<th>Condyloma Acuminata (Genital Warts)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Definition and Clinical Features</td>
<td>Hyperkeratotic, elevated discrete epithelial growths with papillated surface caused by HPV</td>
<td>Hyperkeratotic, shiny, sharply margination growths</td>
<td>Skin-colored pinhead papules to soft cauliflower like masses in clusters</td>
</tr>
<tr>
<td>Differential Diagnosis</td>
<td>Paring or dermoscopic exam of surface reveals punctate, red-brown specks (thrombosed capillaries)</td>
<td>Paring of surface reveals red-brown papules (capillaries), interruption of epidermal ridges</td>
<td>Often occurs in young adults, infants, children</td>
</tr>
<tr>
<td>Distribution</td>
<td>Molluscum contagiosum, seborheic keratosis, SCC</td>
<td>May need to scrape (“pare”) lesions to differentiate wart from callus and corn (see sidebar, D7)</td>
<td>Condyloma lata (secondary syphilitic lesion, dark field strongly +ve), Molluscum contagiosum, SCC</td>
</tr>
<tr>
<td>HPV Type</td>
<td>Located at trauma sites: fingers, hands, knees of children and teens</td>
<td>Located at pressure sites: metatarsal heads, heels, toes</td>
<td>Sites: genitalia and perianal areas</td>
</tr>
<tr>
<td></td>
<td>At least 80 types are known</td>
<td>Commonly HPV 1, 2, 4, 10</td>
<td>Commonly HPV 6 and 11</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>HPV 16, 18, 31, 33 cause cervical dysplasia, SCC and invasive cancer</td>
</tr>
</tbody>
</table>

- other viruses associated with skin changes, such as measles, roseola, fifth disease, etc.
- see Pediatrics, P57

Yeast Infections

CANDIDIASIS

Etiology
- many species of Candida (70-80% of infections are from Candida albicans)
- opportunistic infection in those with predisposing factors (e.g. trauma, malnutrition, immunodeficiency)

Candidal Paronychia
- painful red swellings of periungual skin
- management: topical agents not as effective; oral antifungals recommended

Candidal Intertrigo
- macerated/eroded erythematous patches that may be covered with papules and pustules, located in intertriginous areas often under breast, groin, or interdigitally
- peripheral "satellite" pustules

Treatment for Warts
- **First line Therapies**: salicylic acid preparations (patches, solutions, creams, ointments), cryotherapy, topical cantharone
- **Second Line Therapies**: topical imiquimod, topical 5-fluorouracil, topical tretinoin, podophyllotoxin
- **Third Line Therapies**: curettage, cautery, surgery for non plantar warts, CO2 laser, oral cimetidine (particularly children), intralesional bleomycin (plantar warts), trichloroacetic acid, diphenycpronex
Dermatology Infections Essential Med Notes 2015

• predisposing factors: obesity, DM, systemic antibiotics, immunosuppression, malignancy
• starts as non-infectious maceration from heat, moisture and friction
• management: keep area dry, terbinafine, ciclopirox olamine, ketoconazole/clotrimazole cream bid until rash clears

PITYRIASIS (TINEA) VERSICOLOR

Clinical Presentation
• asymptomatic superficial fungal infection with finely scaling macules of various colors. In caucasian skin often red-brown to light brown, in darker skin tones often light brown to pale (thus versicolor)
• In Caucasians affected skin darker than surrounding skin in winter, lighter in summer (does not tan)
• common sites: upper chest and back

Pathophysiology
• microbe produces carboxylic acid \( \rightarrow \) inflammatory reaction inhibiting melanin synthesis yielding variable pigmentation
• affinity for sebaceous glands; require fatty acids to survive

Etiology
• Pityrosporum ovale (Malassezia furfur)
• also associated with folliculitis and seborrheic dermatitis
• predisposing factors: summer, tropical climates, excessive sweating, Cushing’s syndrome, prolonged corticosteroid use

Investigations
• clinical diagnosis but can perform microscopic examination, KOH prep of scales for hyphae and spores

Management
• ketoconazole shampoo or cream daily
• topical terbinafine or ciclopirox olamine bid
• systemic fluconazole or itraconazole for 7 d if extensive

Sexually Transmitted Diseases

SYPHILIS

Clinical Presentation
• characterized initially by a painless ulcer (chancre)
• following inoculation, systemic infection with secondary and tertiary stages

Etiology
• Treponema pallidum
• transmitted sexually, congenitally, or rarely by transfusion

Table 18. Stages of Syphilis

<table>

</tbody>
</table>
| Oral Terbinafine (Lamisil(\( ^\text{TM} \)) is not effective because it is not secreted by sweat glands

Natural History of Untreated Syphilis
• Inoculation
• Primary syphilis (10-90 d after infection)
• Secondary syphilis (simultaneous to primary syphilis or up to 6 mo after healing of primary lesion)
• Latent syphilis
• Tertiary syphilis (2-20 yr)

Latent Syphilis
70% of untreated patients will remain in this stage for the rest of their lives and are immune to new primary infection
GONOCOCCEMIA

Clinical Presentation
- disseminated gonococcal infection
- hemorrhagic, tender, pustules on a purpuric/petechial background
- common sites: distal aspects of extremities
- associated with fever, arthritis, urethritis, proctitis, pharyngitis, and tenosynovitis
- neonatal conjunctivitis if infected via birth canal

Etiology
- *Neisseria gonorrhoeae*

Investigations
- requires high index of clinical suspicion plays because tests are often negative
- bacterial culture of blood, joint fluid, and skin lesions
- joint fluid cell count and Gram stain

Management
- notify Public Health authorities
- screen for other STDs
- cefixime 400 mg PO (drug of choice) or ceftriaxone 125 mg IM

HSV
- see Viral Infections, D27

HPV
- see Viral Infections, D29

Pre-Malignant Skin Conditions

Actinic Keratosis (Solar Keratosis)

Clinical Presentation
- ill-defined, scaly erythematous papules or plaques on a background of sun-damaged skin (solar heliosis)
- sandpaper-like, gritty sensation felt on palpation, often easier to appreciate on palpation rather than inspection
- sites: areas of sun exposure (face, ears, scalp if bald, neck, sun-exposed limbs)

Pathophysiology
- UV radiation damage to keratinocytes from repeated sun exposure (especially UVB)
- risk of transformation of AK to SCC (~1/1,000), but higher likelihood if AK is persistent

Epidemiology
- common with increasing age, outdoor occupation, M>F
- skin phototypes I-III, rare in darker skin as melanin is protective

Differential Diagnosis
- SCC in situ, superficial BCC, seborrheic keratosis, cutaneous lupus erythematosus

Investigations
- biopsy lesions that are refractory to treatment

Management
- destructive: cryotherapy, electrodessication and curettage
- pharmacotherapy: 5-fluorouracil cream for 2-3 wk, imiquimod cream for 8-10 wk, photodynamic therapy
- excision

Types of AK
- Erythematous: typical AK lesion
- Hypertrophic: thicker, rough papule/plaque
- Cutaneous horn: firm hyperkeratotic outgrowth
- Actinic cheilitis: confluent AKs on the lip
- Pigmented: flat, tan-brown, scaly plaque
- Spreading pigmented
- Proliferative
- Conjunctival: pinguecula, pterygium
**Leukoplakia**

**Clinical Presentation**
- A morphologic term describing homogenous or speckled white plaques with sharply demarcated borders.
- Sites: oropharynx, most often floor of the mouth, soft palate, and ventral/lateral surfaces of the tongue.

**Pathophysiology**
- Precancerous or premalignant condition.
- Oral form is strongly associated with tobacco use and alcohol consumption, although also occurs in congenital disease e.g., dyskeratosis congenita.

**Epidemiology**
- 1-5% prevalence in the adult population after 30 yr of age; peak at age 50.
- M>F, fair-skinned.
- Most common oral mucosal premalignant lesion.

**Differential Diagnosis**
- Lichen planus, oral hairy leukoplakia, mild oral candidiasis.

**Investigations**
- Biopsy is mandatory because it is premalignant.

**Management**
- Low risk sites on buccal/labial mucosal or hard palate: eliminate carcinogenic habits, follow-up.
- Moderate/dysplastic lesions: excision, cryotherapy.

**Malignant Skin Tumors**

**Non-Melanoma Skin Cancers**

**Basal Cell Carcinoma**

**Subtypes**
- Noduloulcerative (typical)
  - Skin-colored papule/nodule with rolled, translucent (“pearly”) telangiectatic border and depressed/eroded/ulcerated center.
- Pigmented variant
  - Flecks of pigment in translucent lesion with surface telangiectasia.
  - May mimic malignant melanoma or seborrheic keratosis clinically.
- Superficial variant
  - Flat, tan to red-brown plaque, often with scaly, pearly border and fine telangiectasia at margin.
  - Least aggressive subtype.
- Sclerosing (morpheaform) variant
  - Flesh/yellowish-colored, shiny papule/plaque with indistinct borders, indurated.

**Pathophysiology**
- Malignant proliferation of basal keratinocytes of the epidermis.
- Low grade cutaneous malignancy, locally aggressive (primarily tangential growth), rarely metastatic.
- Usually due to UVB light exposure, therefore >80% on face.
- May also occur in previous scars, radiation, trauma, arsenic exposure, or genetic predisposition (Gorlin syndrome).

**Epidemiology**
- Most common malignancy in humans.
- 75% of all malignant skin tumors >40 yr, increased prevalence in the elderly.
- M>F, skin phototypes I and II, chronic cumulative sun exposure.

**Differential Diagnosis**
- Benign: sebaceous hyperplasia, intradermal melanocytic nevus, dermatofibroma.
- Malignant: nodular MM, SCC.

**Management**
- Imiquimod 5% cream (Aldara®), 5-Flurouracil (efudex) or cryotherapy is indicated for superficial BCCs on the trunk smaller than 2 cm.
• excision or electrodessication and curettage for most types of BCCs < 2 cm and not on face, not including morpheaform
• Mohs surgery: microscopically controlled, minimally invasive, stepwise excision for lesions on the face or in areas that are difficult to reconstruct or recurrent lesions
• radiotherapy used in advanced cases of BCC where surgical intervention is not an option
• life-long follow-up
• 95% cure rate if lesion <2 cm in diameter or if treated early
• vismodegib for metastatic disease

SQUAMOUS CELL CARCINOMA

Clinical Presentation
• indurated erythematous nodule/plaque with surface scale/crust ± ulceration
• more rapid enlargement than BCC
• sites: face, ears, scalp, forearms, dorsum of hands

Pathophysiology
• malignant neoplasm of keratinocytes (primarily vertical growth)
• predisposing factors include: UV radiation, PUVA, ionizing radiation therapy/exposure, chemical carcinogens (such as arsenic, tar and nitrogen mustards), HPV 16, 18, immunosuppression
• may occur in previous scar (SCC more commonly than BCC)

Epidemiology
• second most common type of cutaneous neoplasm
• primarily on sun-exposed skin in the elderly, M>F, skin phototypes I and II, chronic sun exposure
• in organ transplant recipients SCC is most common cutaneous malignancy, with increased mortality as compared to non-immunocompromised population

Differential Diagnosis
• benign: nummular eczema, psoriasis, irritated seborrheic keratosis, wart
• malignant: keratoacanthoma, Bowen's disease, BCC

Management
• surgical excision with primary closure, skin flaps or grafting
• Mohs surgery
• lifelong follow-up (more aggressive treatment than BCC)

Prognosis
• good prognostic factors: early treatment, negative margins, and small size of lesion
• SCCs that arise from AK metastasize less frequently (~1%) than other SCCs arising de novo in old burns (2-5% of cases)
• overall control is 75% over 5 yr, 5-10% metastasize

OTHER FORMS OF SQUAMOUS CELL CARCINOMA (SCC)

BOWEN'S DISEASE (SQUAMOUS CELL CARCINOMA IN SITU)

Clinical Presentation
• sharply demarcated erythematous plaque with scale and/or crusting
• often 1-3 cm in diameter and found on the skin and mucous membranes
• evolves to SCC in 10-20% of cutaneous lesions and >20% of mucosal lesions

Management
• same as for BCC
• biopsy required for diagnosis
• topical 5-fluorouracil (Efudex®) or imiquimod (Aldara®) used if extensive and as a tool to identify margins of poorly defined tumors
• cryosurgery
• shave excision with electrodessication and curettage

KERATOACANTHOMA

Clinical Presentation
• rapidly growing, firm, dome-shaped, erythematous or skin-colored nodule with central keratin-filled crater, resembling an erupting volcano
• may spontaneously regress within a year, leaving a scar
• sites: sun-exposed skin
Pathophysiology
- epithelial neoplasm with atypical keratinocytes in epidermis
- low grade variant of SCC

Etiology
- HPV, UV radiation, chemical carcinogens (tar, mineral oil)

Epidemiology
- >50 yr, rare <20 yr

Differential Diagnosis
- treat as SCC until proven otherwise
- hypertrophic solar keratosis, verruca vulgaris

Management
- surgical excision or saucerization (shave biopsy) followed by electrodessication of the base, treated similarly to SCC

Malignant Melanoma

Clinical Presentation
- malignant characteristics of a mole: “ABCDE” mnemonic
- sites: skin, mucous membranes, eyes, CNS

Clinical Subtypes of Malignant Melanoma
- lentigo maligna
  - malignant melanoma in situ (normal and malignant melanocytes confined to the epidermis)
  - 2-6 cm, tan/brown/black uniformly flat macule or patch with irregular borders
  - lesion grows radially and produces complex colors
  - often seen in the elderly
  - 10% evolve to lentigo maligna melanoma
- lentigo maligna melanoma (15% of all melanomas)
  - malignant melanocytes invading into the dermis
  - associated with pre-existing solar lentigo, not pre-existing nevi
  - flat, brown, stain-like, gradually enlarging with loss of skin surface markings
  - with time, color changes from uniform brown to dark brown with black and blue
  - found on all skin surfaces, especially those often exposed to sun, such as the face and hands
- superficial spreading melanoma (60-70% of all melanomas)
  - atypical melanocytes initially spread laterally in epidermis then invade the dermis
  - irregular, indurated, enlarging plaques with red/white/blue discoloration, focal papules or nodules
  - ulcerate and bleed with growth
- nodular melanoma (30% of all melanomas)
  - atypical melanocytes that initially grow vertically with little lateral spread
  - uniformly ulcerated, blue-black, and sharply delineated plaque or nodule
  - rapidly fatal
  - may be pink or have no color at all, this is called an amelanotic melanoma
  - “EFG” Elevated, Firm, Growing
- acrolentiginous melanoma (5% of all melanomas)
  - ill-defined dark brown, blue-black macule
  - palmar, planter, subungual skin
  - melanomas on mucous membranes have poor prognosis

Pathophysiology
- malignant neoplasm of pigment forming cells (melanocytes and nevus cells)

Epidemiology
- incidence 1/75 (Canada) 1/50 (US)
- risk factors: numerous moles, fair skin, red hair, positive personal/family history, large congenital nevi, familial dysplastic nevus syndrome, multiple dysplastic nevi
- most common sites: back (M), calves (F)
- worse prognosis if: male, on scalp, hands, feet, late lesion, no pre-existing nevus present

Differential Diagnosis
- benign: nevi, solar lentigo, seborrheic keratosis
- malignant: pigmented BCC

Risk Factors for Melanoma
- no SPF is a SIN
- Sun exposure
- Pigment traits (blue eyes, fair/red hair, pale complexion)
- Freckling
- Skin reaction to sunlight (increased incidence of sunburn)
- Immunosuppressive states (e.g. renal transplantation)
- Nevi (dysplastic nevi; increased number of benign melanocytic nevi)
Management

- excisional biopsy preferable, otherwise incisional biopsy as staged by depth so shave will not be adequate
- remove full depth of dermis and extend beyond edges of lesion only after histologic diagnosis, except for small lesions (removed entirely at biopsy and additional incisional biopsy if positive)
- beware of lesions that regress – tumor is usually deeper than anticipated
- high dose IFN for stage II (regional), chemotherapy (cis-platinum, BCG) and high dose IFN for stage III (distant) disease
- newer chemotherapeutic, gene therapies and vaccines starting to be used in metastatic melanoma
- radiotherapy may be used as adjunctive treatment

Other Cutaneous Cancers

CUTANEOUS T-CELL LYMPHOMA

Clinical Presentation

- **Mycosis fungoides** (limited superficial type)
  - characterized by erythematous patches/plaques/nodules/tumors, which may be pruritic and poikilodermic (atrophy, telangiectasia, hyperpigmentation)
  - common sites include: trunk, buttocks, proximal limbs
  - mildly symptomatic, usually excellent prognosis for early disease
- **Sézary syndrome** (widespread systemic type)
  - rare variant characterized by erythroderma, lymphadenopathy, WBC >20 x 10^9/L with Sézary cells
  - associated with intense pruritus, alopecia, palmoplantar hyperkeratosis, and systemic symptoms (fatigue, fever)
  - often fatal

Pathophysiology

- clonal proliferation of skin-homing CD4 T-cells

Epidemiology

- >50 yr old, M:F 2:1

Differential Diagnosis

- tinea corporis, nummular dermatitis, psoriasis, DLE, Bowen’s disease

Investigations

- skin biopsy (histology, "lymphocyte antigen cell" markers, TcR gene arrangement), epidermoptropism, atypical lymphocytes and loss of CD5 and CD7 markers
- blood smear looking for Sézary cells or flow cytometry (e.g. CD4:CD8 >10 is Sézary)
- imaging (for systemic involvement)

Management

- **Mycosis fungoides**
  - treatment is dependent on stage of disease
  - for patch stage: topical steroids and/or PUVA, narrow band (311-313 mm), UVB (NBUVB)
  - plaque stage: steroids, topical nitrogen mustard, bexarotene, IFN, chemotherapeutic agent
- **Sézary syndrome**
  - oral retinoids and IFN
  - extra-corporeal photophoresis
  - may need radiotherapy for total skin electron beam radiation
  - may maintain on UV therapy
  - other chemotherapeutic agents
Alopecia (Hair Loss)

Hair Growth

- hair grows in a cyclic pattern that is defined in 3 stages
  1. growth stage = anagen phase
  2. transitional stage = catagen stage
  3. resting stage = telogen phase
- total duration of the growth stage reflects the type and location of hair: eyebrow, eyelash, and axillary hairs have a short growth stage in relation to the resting stage
- growth of the hair follicles is also based on the hormonal response to testosterone and DHT; this response is genetically controlled

Non-Scarring (Non-Cicatricial) Alopecia

ANDROGENETIC ALOPECIA

Clinical Presentation
- male- or female-pattern alopecia
- males: fronto-temporal areas progressing to vertex, entire scalp may be bald
- females: widening of central part, “Christmas tree” pattern

Pathophysiology
- action of testosterone on hair follicles

Epidemiology
- males: early 20s-30s
- females: 40s-50s

Management
- minoxidil (Rogaine®) solution or foam to reduce rate of loss/partial restoration
- spironolactone in women (anti-androgenic effects), cyproterone acetate (Diane-35®)
- finasteride (Propecia®) (5-α-reductase inhibitor) 1 mg/d in men
- hair transplant

PHYSICAL
- trichotillomania: impulse-control disorder characterized by compulsive hair pulling with irregular patches of hair loss, and with remaining hairs broken at varying lengths
- traumatic (e.g. tight “corn-row” braiding of hair, wearing tight pony tails, tight tying of turbans)

TELOGEN EFFLUVIOUM

Clinical Presentation
- uniform decrease in hair density secondary to hairs leaving the growth (anagen) stage and entering the resting (telogen) stage of the cycle

Pathophysiology
- variety of precipitating factors (see sidebar)
- hair loss typically occurs 2-4 mo after exposure to precipitant
- regrowth occurs within a few months but may not be complete

ANAGEN EFFLUVIOUM

Clinical Presentation
- hair loss due to insult to hair follicle impairing its mitotic activity (growth stage)

Pathophysiology
- precipitated by chemotherapeutic agents (most common), other meds (bismuth, levodopa, colchicine, cyclosporine), exposure to chemicals (thallium, boron, arsenic)
- dose-dependent effect
- hair loss 7-14 d after single pulse of chemotherapy; most clinically apparent after 1-2 mo
- reversible effect; follicles resume normal mitotic activity few weeks after agent stopped
ALOPECIA AREATA

Clinical Presentation
- autoimmune disorder characterized by patches of complete hair loss often localized to scalp but can affect eyebrows, beard, eyelashes, etc.
- may be associated with dystrophic nail changes – fine stippling, pitting
- "exclamation mark" pattern (hairs fractured and have tapered shafts, i.e. looks like "!")
- may be associated with pernicious anemia, vitiligo, thyroid disease, Addison's disease
- spontaneous regrowth may occur within months of first attack (worse prognosis if young at age of onset and extensive loss)
- frequent recurrence often precipitated by emotional distress

Management
- generally unsatisfactory
- intralesional triamcinolone acetonide (corticosteroids) can be used for isolated patches
- UV or PUVA therapy
- immunomodulatory (diphencyprone)

Scarring (Cicatricial) Alopecia

Clinical Presentation
- irreversible loss of hair follicles with fibrosis

Etiology
- physical: radiation, burns
- infections: fungal, bacterial, TB, leprosy, viral (HZV)
- inflammatory
  - lichen planus (lichen planopilaris)
  - DLE (note that SLE can cause an aloppecia unrelated to DLE lesions which are non-scarring)
  - morphea: "coup de sable" with involvement of center of scalp
- central centrifugal cicatricial alopecia: seen in up to 40% of black women, starting at central scalp; one of most commonly diagnosed scarring alopecias, may be associated with hair care practices in this population

Investigations
- biopsy from active border

Management
- infections: treat underlying infection
- inflammatory: topical/intralesional steroids, anti-inflammatory antibiotics, antimalarials, immunosuppressants, oral steroids, retinoids, thalidomide

Nails and Disorders of the Nail Apparatus

Table 20. Nail Changes in Systemic and Dermatological Conditions

**Pediatric Exanthems**

- see Pediatrics, P57

**Miscellaneous Lesions**

**Angioedema and Urticaria**

**Angioedema**
- deeper swelling of the skin involving subcutaneous tissues; often involves the eyes, lips, and tongue
- may or may not accompany urticaria
- hereditary or acquired forms
- hereditary angioedema (does not occur with urticaria)
  - onset in childhood; 80% have positive family history
  - recurrent attacks; 25% die from laryngeal edema
  - triggers: minor trauma, emotional upset, temperature changes
- types of acquired angioedema
  - acute allergic angioedema (allergens include food, drugs, contrast media, insect venom, latex)
  - non-allergic drug reaction (drugs include ACE inhibitors)
  - acquired C1 inhibitor deficiency
- treatment
  - prophylaxis with danazol or stanozolol for hereditary angioedema
  - epinephrine pen to temporize until patient reaches hospital in acute attack

**Urticaria**
- also known as “hives”
- transient, red, pruritic well-demarcated wheals
- each individual lesion lasts less than 24 h
- second most common type of drug reaction
- results from release of histamine from mast cells in dermis
- can also result after physical contact with allergen
- treatment with oral antihistamines in high dosages, oral steroids, immunosuppressives (mycophenolate mofetil, Imuran) or newly approved omalizumab

</table>

Clinical Presentation
- acute or chronic inflammation of subcutaneous fat (panniculitis)
- round, red, tender, poorly demarcated nodules
- sites: asymmetrically arranged on extensor lower legs (typically shins) much less commonly knees, arms
- associated with arthralgia, fever, malaise

Etiology
- 40% are idiopathic
- drugs: sulfonamides, OCPs (also pregnancy), analgesics, trans retinoic acid
- infections: GAS, TB, histoplasmosis, Yersinia
- inflammation: sarcoidosis, Crohn’s > UC
- malignancy: acute leukemia, Hodgkin's lymphoma

Epidemiology
- 15-30 yr old, F:M = 3:1
- lesions last for days and spontaneously resolve in 6 wk, although some patients will have chronic recurrence secondary to underlying conditions

Investigations
- chest X-ray (to rule out chest infection and sarcoidosis)
- throat culture, ASO titre, PPD skin test

Management
- symptomatic: bed rest, compressive bandages, wet dressings
- NSAIDs, intralesional steroids
- treat underlying cause
- super saturated potassium iodide with thyroid monitoring, dapsone and colchicine

DDx of Erythema Nodosum

- NODOSUMM
  - No cause (idiopathic) in 40%
  - Drugs (sulfonamides, OCP, etc.)
  - Other infections (GAS+)
  - Sarcoidosis
  - UC and Crohn’s
  - Malignancy (leukemia, Hodgkin’s lymphoma)
  - Many infections

Approach to Urticaria
- Thorough Hx and P/E
- Acute: no immediate investigations needed; consider referral for allergy testing
- Chronic: further investigations required: CBC and differential, urinalysis, ESR, TSH, LFTs to help identify underlying cause
- Vasculitic: biopsy of lesion and referral to dermatology

Mastocytosis (Urticaria Pigmentosa)
Rare disease due to excessive infiltration of the skin by mast cells. It manifests as many reddish-brown elevated plaques and macules. Friction to a lesion produces a wheal surrounded by intense erythema (Darier’s sign), due to mast cell degranulation; this occurs within minutes
Pruritus

Clinical Presentation
- a sensation provoking a desire to scratch, with or without skin lesions
- lesions may arise from the underlying disease, or from excoriation causing crusts, lichenified plaques, or wheals

Etiology
- dermatologic – generalized
  - astematous dermatitis (“winter itch” due to dry skin)
  - pruritus of senescent skin (may not have dry skin, any time of year)
  - infestations: scabies, lice
  - drug eruptions: ASA, antidepressants, opiates
  - psychogenic states
- dermatologic – local
  - atopic and contact dermatitis, lichen planus, urticaria, insect bites, dermatitis herpetiformis
  - infection: varicella, candidiasis
  - lichen simplex chronicus
  - prurigo nodularis
- systemic disease – usually generalized
  - hepatic: obstructive biliary disease, cholestatic liver disease of pregnancy
  - renal: chronic renal failure, uremia secondary to hemodialysis
  - hematologic: Hodgkin’s lymphoma, multiple myeloma, leukemia, polycythemia vera, hemochromatosis, Fe deficiency anemia, cutaneous T-cell lymphoma
  - neoplastic: lung, breast, gastric (internal solid tumors), non-Hodgkin’s lymphoma
  - endocrine: carcinoid, DM, hypothyroid/thyrotoxicosis
  - infectious: HIV, trichinosis, echinococcosis, hepatitis C
  - psychiatric: depression, psychosis
  - neurologic: post-herpetic neuralgia, multiple sclerosis

Investigations
- detailed history
- complete physical, including rectal and pelvic examination
- blood work: CBC, ESR, Cr/BUN, LFT, TSH, fasting blood sugar, stool culture and serology for parasites, if on palms with no rash check bile acids, especially in pregnancy

Management
- treat underlying cause
- cool water compresses to relieve pruritus
- bath oil and emollient ointment (especially if xerosis is present)
- topical corticosteroid and antipruritics (e.g. menthol, camphor, phenol, mirtazapine, capsaicin)
- systemic antihistamines: H1 blockers are most effective, most useful for urticaria
- phototherapy with UVB or PUV A
- doxepin, amitryptyline
- gabapentin, pregabalin
- naloxone
- immunosuppressive agents if severe: steroids and steroid sparing

Wounds and Ulcers
- see Plastic Surgery. PS8, PS15

Common Medications

Sunscreens and Preventative Therapy

Sunburn
- erythema 2-6 h post UV exposure often associated with edema, pain and blistering with subsequent desquamation of the dermis, and hyperpigmentation
- chronic UVA, UVB exposure leads to photoaging, immunosuppression, photocarcinogenesis
- prevention: avoid peak UVR (10 am to 4 pm), wear appropriate clothing, wide-brimmed hat, sunglasses, and broad-spectrum sunscreen
- clothing with UV protection expressed as UV protection factor (UPF) is analogous to SPF of sunscreen

Sunscreens
- under ideal conditions an SPF of 10 means that a person who normally burns in 20 min will burn in 200 min following the application of the sunscreen but by definition SPF relates ONLY to UVB absorption.
• topical chemical: absorbs UV light
  - requires application at least 15-60 min prior to exposure, should be reapplied every 2 h (more often if sweating, swimming)
  - UVB absorbers: PABA, salicylates, cinnamates, benzylidene camphor derivatives
  - UVA absorbers: benzophenones, anthranilates, dibenzoylmethanes, benzylidene camphor derivatives
• topical physical: reflects and scatters UV light
  - titanium dioxide, zinc oxide, kaolin, talc, ferric chloride, and melanin
  - all are effective against the UVA and UVB spectrum
  - less risk of sensitization than chemical sunscreens and waterproof, but may cause folliculitis or miliaria
• some sunscreen ingredients may cause contact or photocontact allergic reactions, but are uncommon

Management
• sunburn: if significant blistering present, consider treatment in hospital; otherwise, symptomatic treatment (cool wet compresses, oral anti-inflammatory, topical corticosteroids)
• antioxidants, both oral and topical are being studied for their abilities to protect the skin; topical agents are limited by their ability to penetrate the skin

Topical Steroids

</tr>
</tbody>
</table>

Surface Area

- 30 g covers full adult body once. Children have a greater surface area/volume ratio and there are consequently greater side effects

UV Radiation

- UVA (320-400 nm): Aging
  - Penetrates skin more effectively than UVB or UVC
  - Responsible for tanning, burning, wrinkling, photoageing and premature skin aging
  - Penetrates clouds, glass and is reflected off water, snow and cement
- UVB (290-320 nm): Burning
  - Absorbed by the outer dermis
  - Is mainly responsible for burning and premature skin aging
  - Primarily responsible for BCC, SCC
  - Does not penetrate glass and is substantially absorbed by ozone
- UVC (200-290 nm)
  - Is filtered by ozone layer

Initial Patient Assessment/Management

1. Rapid Primary Survey

- Airway maintenance with cervical spine (C-spine) control
- Breathing and ventilation
- Circulation (pulses, hemorrhage control)
- Disability (neurological status)
- Exposure (complete) and Environment (temperature control)
- Continually reassessed during secondary survey
- **IMPORTANT**: always watch for signs of shock while doing primary survey

**A. AIRWAY**
- First priority is to secure airway
- Assume a cervical injury in every trauma patient and immobilize with collar
- Assess ability to breathe and speak
- Can change rapidly, therefore reassess frequently

**Airway Management**
- Permit adequate oxygenation and ventilation

1. **Basic Airway Management**
   - Protect the C-spine
   - Head-tilt (if C-spine injury not suspected) or jaw thrust to open the airway
   - Sweep and suction to clear mouth of foreign material

2. **Temporizing Measures**
   - Nasopharyngeal airway (if gag reflex present, i.e. conscious)
   - Oropharyngeal airway (if gag reflex absent, i.e. unconscious)
   - “Rescue” airway devices (e.g. laryngeal mask airway, Combitube®)
   - Transvascular jet ventilation through cricothyroid membrane (last resort)

3. **Definitive Airway Management**
   - ETT intubation with in-line stabilization of C-spine
     - Oropharyngeal ± RSI preferred
     - Nasotracheal may be better tolerated in conscious patient
     - Relatively contraindicated with basal skull fracture
     - Does not provide 100% protection against aspiration
   - Surgical airway (if unable to intubate using oral/nasal route and unable to ventilate)
     - Cricothyroidotomy

**Contraindications to Intubation**
- Supraglottic/glottic pathology that would preclude successful intubation
Figure 1. Approach to endotracheal intubation in an injured patient

B. BREATHING

- **Look**
  - mental status (anxiety, agitation, decreased LOC), color, chest movement (bilateral vs. asymmetrical), respiratory rate/effort, nasal flaring

- **Listen**
  - auscultate for signs of obstruction (e.g. stridor), breath sounds, symmetry of air entry, air escaping

- **Feel**
  - tracheal shift, chest wall for crepitus, flail segments, sucking chest wounds, subcutaneous emphysema

Breathing Assessment
- objective measures of respiratory function: rate, oximetry, ABG, A-a gradient

Management of Breathing
- nasal prongs → simple face mask → non-rebreather mask → CPAP/BiPAP (in order of increasing F\textsubscript{IO\textsubscript{2}})
- Venturi mask: used to precisely control O\textsubscript{2} delivery
- Bag-Valve mask and CPAP to supplement inadequate ventilation

C. CIRCULATION

Definition of Shock
- inadequate organ and tissue perfusion with oxygenated blood (brain, kidney, extremities)

Table 1. Major Types of Shock

Management of Hemorrhagic Shock
- ABCs
- diagnose and manage underlying cause
- if bleeding externally, apply direct pressure and elevate extremities if possible
  - do not remove impaled objects as they tamponade hemorrhage
  - tourniquet as a last resort
- resuscitation
  - infuse 1-2 L of crystalloid with large bore IVs (warmed if possible)
  - if inadequate response, consider active internal bleeding (e.g. chest, abdomen, pelvis, femurs), will likely require surgical intervention
  - if severely hypotensive on arrival or if shock persists, consider pRBC transfusion
  - transfuse crossmatched (ideally) or type-specific blood if available
  - if unavailable, transfuse O-negative in children/women of childbearing age or O-positive in all others
- with significant blood loss, early transfusion of platelets and FFP may improve outcomes

D. DISABILITY
- assess LOC using GCS
- pupils
  - inequality, size, symmetry, reactivity to light
    - inequality/sluggish suggests local eye problem or lateralizing CNS lesion
    - relative afferent pupillary defect (swinging light test) – optic nerve damage
    - extraocular movements and nystagmus
    - fundoscopy (papilledema, hemorrhages)
  - reactive pupils + decreased LOC → metabolic or structural cause
  - non-reactive pupils + decreased LOC → structural cause (especially if asymmetric)

Glasgow Coma Scale
- for use in trauma patients with decreased LOC; good indicator of severity of injury and neurosurgical prognosis
- most useful if repeated; change in GCS with time is more relevant than the absolute number
- less meaningful for metabolic coma
- patient with deteriorating GCS needs immediate attention
- prognosis based on best post-resuscitation GCS
- reported as a 3 part score: Eyes + Verbal + Motor = Total
  - if patient intubated, GCS score reported out of 10 + T (T = tubed, i.e. no verbal component)

Table 3. Glasgow Coma Scale

13-15 = mild injury, 9-12 = moderate injury, ≤8 = severe injury

Unilateral, Dilated, Non-Reactive Pupil, Think:
- Focal mass lesion
- Epidural hematoma
- Subdural hematoma

E. EXPOSURE/ENVIRONMENT
- undress patient completely and assess entire body for injury; log roll to examine back
- DRE
- keep patient warm with a blanket ± radiant heaters; avoid hypothermia
- warm IV fluids/blood
- keep providers safe (contamination, combative patient)

2. Resuscitation
- done concurrently with primary survey
- attend to ABCs
- manage life-threatening problems as they are identified
- vital signs q5-15 min
- ECG, BP, and O₂ monitors
- Foley catheter and NG tube if indicated
- tests and investigations: CBC, electrolytes, BUN, Cr, glucose, amylase, INR/PTT, ß-hCG, toxicology screen, cross and type

3. Secondary Survey

- done after rapid primary survey problems have been addressed
- identifies major injuries or areas of concern
- full physical exam and x-rays (C-spine, chest, pelvis – required in blunt trauma, consider T-spine and L-spine)

HISTORY

- "SAMPLE": Signs and symptoms, Allergies, Medications, Past medical history, Last meal, Events related to injury

---

**FAST view: Normal**

- heart chambers
- pericardial effusion (E)

**FAST view: Free Fluid**

1. **1. Subxiphoid Pericardial Window**
- spleen (S), L kidney (K)
- free fluid (F)

2. **2. Perisplenic**
- liver (L), kidney (K)
- blood (BL)

3. **3. Hepatorenal (Morrison’s Pouch)**
- bladder (B)
- free fluid (F)

© Ashley Hui 2015

Figure 2. Four areas of a FAST
PHYSICAL EXAM

Head and Neck
- palpation of facial bones, scalp

Chest
- inspect for midline trachea, flail segment; ≥2 rib fractures in ≥2 places; if present look for associated hemothorax, pneumothorax, and contusions
- auscultate lung fields
- palpate for subcutaneous emphysema
- CXR

Abdomen
- assess for peritonitis, abdominal distention, and evidence of intra-abdominal bleeding
- FAST or CT (if stable)
- rectal exam for GI bleed, high riding prostate and anal tone (best to do during the log roll)
- bimanual exam in females as appropriate

Musculoskeletal
- examine all extremities for swelling, deformity, contusion, tenderness, ROM
- check for pulses and sensation in all injured limbs
- log roll and palpate thoracic and lumbar spines
- palpate iliac crests and pubic symphysis, pelvic stability (lateral, AP, vertical)
- pelvic x-ray

Neurological
- GCS
- full cranial nerve exam
- alterations of rate and rhythm of breathing are signs of structural or metabolic abnormalities
  - progressive deterioration of breathing pattern implies a failing CNS
- assess spinal cord integrity
  - conscious patient: assess distal sensation and motor
  - unconscious patient: response to painful or noxious stimulus applied to extremities

Ethical Considerations

Consent to Treatment: Adults
- see Ethical, Legal, and Organizational Medicine, ELOAM5
- Emergency Rule: consent is not needed when a patient is at imminent risk from a serious injury
- AND obtaining consent is either: a) not possible, OR b) would increase risk to the patient
  - assumes that most people would want to be saved in an emergency
- any capable and informed patient can refuse treatment or part of treatment, even if it is life-saving
- exceptions to the Emergency Rule: treatment cannot be initiated if:
  - a competent patient has previously refused the same or similar treatment and there is no evidence to suggest the patient's wishes have changed
  - an advanced directive is available (e.g. do not resuscitate order)
  - NOTE: refusal of help in a suicide situation is NOT an exception; care must be given
- if in doubt, initiate treatment
  - care can be withdrawn if necessary at a later time or if wishes are clarified by family

Consent to Treatment: Children
- treat immediately if patient is at imminent risk
- parents/guardians have the right to make treatment decisions
- if parents refuse treatment that is life-saving or will potentially alter the child's quality of life, CAS must be contacted – consent of CAS is needed to treat

Other Issues of Consent
- need consent for HIV testing, as well as for administration of blood products
- however, if delay in substitute consent for blood transfusions puts patient at risk, transfusions can be given

Duty to Report
- law may vary depending on state
- examples: gunshot wounds, potential drunk drivers, suspected child abuse, various communicable diseases, medical unsuitability to drive, risk of substantial harm to others
Traumatology

- Epidemiology
  - Leading cause of death in patients <45 yr
  - 4th highest cause of death in North America
  - Causes more deaths in children/adolescents than all diseases combined

- Trimodal distribution of death
  - Minutes: lethal injuries, death usually at the scene
  - Early: death within 4-6 h – “golden hour” (decreased mortality with trauma care)
  - Days-weeks: death from multiple organ dysfunction, sepsis, etc.

- Injuries fall into two categories
  - Blunt (most common): MVC, pedestrian-automobile impact, motorcycle collision, fall, assault, sports
  - Penetrating (increasing in incidence): gunshot wound, stabbing, impalement

Considerations for Traumatic Injury

- Important to know the mechanism of injury in order to anticipate traumatic injuries
- Always look for an underlying cause (alcohol, medications, illicit substances, seizure, suicide attempt, medical problem)
- Always inquire about head injury, loss of consciousness, amnesia, vomiting, headache, and seizure activity

Table 5. Mechanisms and Considerations of Traumatic Injuries

<table>
<thead>
<tr>
<th>Mechanism of Injury</th>
<th>Special Considerations</th>
<th>Associated Injuries</th>
</tr>
</thead>
<tbody>
<tr>
<td>Motor Vehicle Collision</td>
<td>Vehicle(s) involved: weight, size, speed, damage Location of patient in vehicle Use and type of seatbelt Ejection of patient from vehicle Entrapment of patient under vehicle Airbag deployment Helmet use in motorcycle collision</td>
<td>Head-on collision: head/facial, thoracic (aortic), lower extremity Lateral/T-bone collision: head, cervical spine, thoracic, abdominal, pelvic, and lower extremity Rear-end collision: hyper-extension of cervical spine (whiplash injury) Rollover</td>
</tr>
<tr>
<td>Pedestrian-Automobile Impact</td>
<td>High morbidity and mortality Vehicle speed is an important factor Site of impact on car</td>
<td>Children at increased risk of being run over (multisystem injuries) Adults tend to be struck in lower legs (lower extremity injuries), impacted against car (truncal injuries), and thrown to ground (HII)</td>
</tr>
<tr>

Head Trauma

- See Neurosurgery, NS29
- 60% of MVC-related deaths are due to head injury

Specific Injuries

- Fractures
  - Dx: non-contrast head CT and physical exam
  - A. Skull fractures
    - Vault fractures
      - Linear, non-depressed
        - Most common
        - Typically occur over temporal bone, in area of middle meningeal artery (commonest cause of epidural hematoma)
      - Depressed
        - Open (associated overlying scalp laceration and torn dura, skull fracture disrupting paranasal sinuses or middle ear) vs. closed
    - Basal skull
      - Typically occur through floor of anterior cranial fossa (longitudinal more common than transverse)
      - Clinical diagnosis superior as poorly visualized on CT
  - B. Facial fractures (see Plastic Surgery, PL28)
  - Neuronal injury
■ beware of open fracture or sinus fractures (risk of infection)
■ severe facial fractures may pose risk to airway from profuse bleeding

• scalp laceration
  ■ can be a source of significant bleeding
  ■ achieve hemostasis, inspect and palpate for skull bone defects ± CT head (rule-out skull fracture)

• neuronal injury
  A. diffuse
  ■ transient alteration in mental status that may involve loss of consciousness
    • hallmark signs of concussion: confusion and amnesia, which may occur immediately after the trauma or min later
    • loss of consciousness (if present) must be less than 30 min, initial GCS must be between 13–15, and post-traumatic amnesia must be less than 24 h
  ■ diffuse axonal injury
    • mild: coma 6–24 h, possibly lasting deficit
    • moderate: coma >24 h, little or no signs of brainstem dysfunction
    • severe: coma >24 h, frequent signs of brainstem dysfunction

B. focal injuries
  • contusions
  • intracranial hemorrhage (epidural, subdural, intracerebral)

ASSESSMENT OF BRAIN INJURY

History
• pre-hospital status
• mechanism of injury

Physical Exam
• assume C-spine injury until ruled out
• vital signs
  • shock (not likely due to isolated brain injury, except in infants)
  • Cushing’s response to increasing ICP (bradycardia, HTN, irregular respirations)
• severity of injury determined by
  1. LOC
    • GCS ≤8 intubate, any change in score of 3 or more = serious injury
    • mild TBI = 13–15, moderate = 9–12, severe = 3–8
  2. pupils: size, anisocoria >1 mm (in patient with altered LOC), response to light
  3. lateralizing signs (motor/sensory)
    • may become more subtle with increasing severity of injury
    • reassess frequently

Investigations
• labs: CBC, electrolytes, PT/PTT or INR/PTT, glucose, toxicology screen
• CT scan (non-contrast) to exclude intracranial mass lesions
• C-spine imaging, often with CT head and neck to exclude intracranial mass lesions

Management
• goal in ED: reduce secondary injury by avoiding hypoxia, ischemia, decreased CPP, seizure
• general
  • ABCs
  • ensure oxygen delivery to brain through intubation and prevent hypercarbia
  • maintain BP (sBP >90)
  • treat other injuries
• early neurosurgical consultation for acute and subsequent patient management
• medical management
  • seizure treatment/prophylaxis
    – benzodiazepines, phenytoin, phenobarbital
    – steroids are of no proven value
  • treat suspected raised ICP → consider if head injury with signs of increased ICP
    – raise head of stretcher 20° if patient hemodynamically stable
    – intubate and hyperventilate (100% O₂) to a pCO₂ of 30–35 mmHg
    – mannitol 1 g/kg infused as rapidly as possible (contraindicated in shock and renal failure/anuria)
    – consider paralyzing medications if agitated/high airway pressures
    – maintenance of CPP is critical (CPP = MAP - ICP)

Disposition
• neurosurgical ICU admission for severe HI
• in hemodynamically unstable patient with other injuries, prioritize most life-threatening injuries and maintain cerebral perfusion
• for minor head injury not requiring admission, provide 24 h HI protocol to competent caregiver, follow-up with neurology as even seemingly minor HI may cause lasting deficits

**Warning Signs of Severe Head Injury**
• GCS <8
• Deteriorating GCS
• Unequal pupils
• Lateralizing signs
N.B: Altered LOC is a hallmark of brain injury

**Canadian CT Head Rule**
Lancet 2001;357:1391-1396
CT Head is only required for patients with minor head injuries with any one of the following:

**High Risk** (for neurological intervention)
• GCS score <15 at 2 h after injury.
• Suspected open or depressed skull fracture.
• Any sign of basal skull fracture (hemotympanum, “racoon” eyes, CSF otorrhea/rhinorrhea, Battle’s sign).
• Vomiting ≥2 episodes.
• Age ≥65 yr.

**Medium Risk** (for brain injury on CT)
• Amnesia before impact >30 min (i.e. cannot recall events just before impact).
• Dangerous mechanism (pedestrian struck by motor vehicle, occupant ejected from motor vehicle, fall from height >3 feet or five stairs).

Minor head injury is defined as witnessed loss of consciousness, definite amnesia, or witnessed disorientation in a patient with a GCS score of 13-15.
N.B: Canadian CT Head Rule does not apply for non-trauma cases, for GCS<13, age <16, for patients on Coumadin® and/or having a bleeding disorder, or having an obvious open skull fracture.
Mild Traumatic Brain Injury

Epidemiology
• TBI results in 1.7 million deaths, hospitalizations, and ED visits each yr (US)
• 75% are estimated to be mild TBI; remainder are moderate or severe (see Neurosurgery, NS31)
• highest rates in children 0-4 yr, adolescents 15-19 yr, and elderly >65 yr

Clinical Features
• somatic: headache, sleep disturbance, N/V, blurred vision
• cognitive dysfunction: attentional impairment, reduced processing speed, drowsiness, amnesia
• emotion and behavior: impulsivity, irritability, depression
• severe concussion: may precipitate seizure, bradycardia, hypotension, sluggish pupils

Etiology
• falls, MVC, and traffic accidents, struck by an object, assault, sports

Investigations
• neurological exam
• concussion recognition tool (see thinkfirst.ca)
• imaging – CT as per Canadian CT Head Rules, or MRI if worsening symptoms despite normal CT

Treatment
• close observation and follow-up; for patients at risk of intracranial complications, give appropriate discharge instructions to patient and family, watch for changes to clinical features above, and if change, return to ED
• hospitalization with normal CT (GCS <15, seizures, bleeding diathesis), or with abnormal CT
• early rehabilitation to maximize outcomes
• pharmacological management of pain, depression, headache
• follow Return to Play guidelines

Prognosis
• most recover with minimal treatment
  ▪ athletes with previous concussion are at increased risk of cumulative brain injury
• repeat TBI can lead to life-threatening cerebral edema or permanent impairment

Spine and Spinal Cord Trauma
• assume cord injury with significant falls (>12 ft), deceleration injuries, blunt trauma to head, neck, or back
• spinal immobilization (cervical collar, spine board during patient transport only) must be maintained until spinal injury has been ruled out (Figure 3)
• vertebral injuries may be present without spinal cord injury; normal neurologic exam does not exclude spinal injury
• cord may be injured despite normal C-spine x-ray (SCIWORA = spinal cord injury without radiologic abnormality)
• injuries can include: complete/incomplete transection, cord edema, spinal shock

History
• mechanism of injury, previous deficits, SAMPLE
• neck pain, paralysis/weakness, paresthesia

Physical Exam
• ABCs
• abdominal: ecchymosis, tenderness
• neurological: complete exam, including mental status
• spine: maintain neutral position, palpate C-spine; log roll, then palpate T-spine and L-spine; assess rectal tone
  ▪ when palpating, assess for tenderness, muscle spasm, bony deformities, step-off, and spinous process malalignment
• extremities: check cap refill, suspect thoracolumbar injury with calcaneal fractures

Investigations
• labs: CBC, electrolytes, Cr, glucose, coagulation profile, cross and type, toxicology screen
• imaging
  ▪ full C-spine x-ray series for trauma (AP, lateral, odontoid)
  ▪ thoracolumbar x-rays
  ▪ AP and lateral views
  ▪ indications
    ▪ patients with C-spine injury
    ▪ unconscious patients (with appropriate mechanism of injury)
    ▪ patients with neurological symptoms or findings

Investigations
• extremities: check cap refill, suspect thoracolumbar injury with calcaneal fractures

Etiology
• falls, MVC, and traffic accidents, struck by an object, assault, sports

Investigations
• neurological exam
• concussion recognition tool (see thinkfirst.ca)
• imaging – CT as per Canadian CT Head Rules, or MRI if worsening symptoms despite normal CT

Treatment
• close observation and follow-up; for patients at risk of intracranial complications, give appropriate discharge instructions to patient and family, watch for changes to clinical features above, and if change, return to ED
• hospitalization with normal CT (GCS <15, seizures, bleeding diathesis), or with abnormal CT
• early rehabilitation to maximize outcomes
• pharmacological management of pain, depression, headache
• follow Return to Play guidelines

Prognosis
• most recover with minimal treatment
  ▪ athletes with previous concussion are at increased risk of cumulative brain injury
• repeat TBI can lead to life-threatening cerebral edema or permanent impairment

Spine and Spinal Cord Trauma
• assume cord injury with significant falls (>12 ft), deceleration injuries, blunt trauma to head, neck, or back
• spinal immobilization (cervical collar, spine board during patient transport only) must be maintained until spinal injury has been ruled out (Figure 3)
• vertebral injuries may be present without spinal cord injury; normal neurologic exam does not exclude spinal injury
• cord may be injured despite normal C-spine x-ray (SCIWORA = spinal cord injury without radiologic abnormality)
• injuries can include: complete/incomplete transection, cord edema, spinal shock

History
• mechanism of injury, previous deficits, SAMPLE
• neck pain, paralysis/weakness, paresthesia

Physical Exam
• ABCs
• abdominal: ecchymosis, tenderness
• neurological: complete exam, including mental status
• spine: maintain neutral position, palpate C-spine; log roll, then palpate T-spine and L-spine; assess rectal tone
  ▪ when palpating, assess for tenderness, muscle spasm, bony deformities, step-off, and spinous process malalignment
• extremities: check cap refill, suspect thoracolumbar injury with calcaneal fractures

Investigations
• labs: CBC, electrolytes, Cr, glucose, coagulation profile, cross and type, toxicology screen
• imaging
  ▪ full C-spine x-ray series for trauma (AP, lateral, odontoid)
  ▪ thoracolumbar x-rays
  ▪ AP and lateral views
  ▪ indications
    ▪ patients with C-spine injury
    ▪ unconscious patients (with appropriate mechanism of injury)
    ▪ patients with neurological symptoms or findings

Spine and Spinal Cord Trauma
• assume cord injury with significant falls (>12 ft), deceleration injuries, blunt trauma to head, neck, or back
• spinal immobilization (cervical collar, spine board during patient transport only) must be maintained until spinal injury has been ruled out (Figure 3)
• vertebral injuries may be present without spinal cord injury; normal neurologic exam does not exclude spinal injury
• cord may be injured despite normal C-spine x-ray (SCIWORA = spinal cord injury without radiologic abnormality)
• injuries can include: complete/incomplete transection, cord edema, spinal shock

History
• mechanism of injury, previous deficits, SAMPLE
• neck pain, paralysis/weakness, paresthesia

  ▪ when palpating, assess for tenderness, muscle spasm, bony deformities, step-off, and spinous process malalignment
• extremities: check cap refill, suspect thoracolumbar injury with calcaneal fractures

Investigations
• labs: CBC, electrolytes, Cr, glucose, coagulation profile, cross and type, toxicology screen
• imaging
  ▪ full C-spine x-ray series for trauma (AP, lateral, odontoid)
  ▪ thoracolumbar x-rays
  ▪ AP and lateral views
  ▪ indications
    ▪ patients with C-spine injury
    ▪ unconscious patients (with appropriate mechanism of injury)
    ▪ patients with neurological symptoms or findings
The Canadian C-Spine Rule
JAMA 2001;286:1841-1848

For Alert (GCS Score = 15) and Stable Trauma Patients where C-Spine Injury is a Concern

1. Any high-risk factor that mandates radiography?
   - Age $\geq 65$ yr
   - Dangerous mechanism*
   - Paresthesias in extremities

   No

2. Any one low-risk factor that allows safe assessment of ROM?
   - Simple rear-end MVC†
   - Sitting position in ED
   - Ambulatory at any time
   - Delayed onset of neck pain§
   - Absence of midline C-spine tenderness

   Yes

3. Able to actively rotate neck?
   >45º left and right

   Able

No radiography

Unable

Figure 3. Approach to clearing the C-spine

Can Clear C-Spine if:
- oriented to person, place, time, and event
- no evidence of intoxication
- no posterior midline cervical tenderness
- no focal neurological deficits
- no painful distracting injuries (e.g. long bone fracture)

Management of Cord Injury
- immobilize
- evaluate ABCs
- treat shock (maintain $sBP > 100$ mmHg)
- insert NG and Foley catheter
- high dose steroids: methylprednisolone 30 mg/kg bolus, then 5.4 mg/kg/h drip, start within 6-8 h of injury (controversial and recently has less support)
- complete imaging of spine and consult spine service if available
- continually reassess high cord injuries as edema can travel up cord
- if cervical cord lesion, watch for respiratory insufficiency
  - low cervical transection (C5-T1) produces abdominal breathing (phrenic innervation of diaphragm still intact)
  - high cervical cord injury (above C4) may require intubation and ventilation
- beware of hypotension (neurogenic shock)
- treatment: warm blanket, Trendelenburg position (occasionally), volume infusion, consider vasopressors

Approach to C-Spine X-Rays
- 3-view C-spine series is the screening modality of choice
  1. lateral C1-T1 ± swimmer’s view
     - lateral view is best, identifies 90-95% of injuries
  2. odontoid view (open mouth or oblique submental view)
     - examine the dens for fractures
     - if unable to rule out fracture, repeat view or consider CT or plain film tomography
     - examine lateral aspects of C1 and spacing relative to C2

- MRIs
- Flexion/extension films
- Abnormal films
- Normal films
- C-spine cleared
- MRI neurologic exam
- Abnormal films
- Remain immobilized, consult spine service
- Normal x-rays, 3 views
- 2. CT scan if:
   - Inadequate plain film survey
   - Suspicious plain film findings
   - To better delineate injuries seen on plain films
   - Any clinical suspicion of atlanto-axial subluxation
   - High clinical suspicion of injury despite normal x-ray
   - To include C1-C3 when head C1 is indicated in head trauma

- Prevertebral soft tissue swelling is only 49% sensitive for injury

Figure 4. Lines of contour on a lateral C-spine x-ray
3. AP view
   • alignment of spinous processes in the midline
   • spacing of spinous processes should be equal
   • check vertebral bodies and facet dislocations

Table 6. Interpretation of Lateral View: The ABCS

A Adequacy and Alignment
   • Must see C1 to C7-T1 junction; if not, downward traction of shoulders, swimmer’s view, bilateral supine obliques, or CT scan needed
   • Lines of contour – in children < 8 yr of age, can see physiologic subluxation of C2 on C3, and C3 on C4, but the spino-laminal line is maintained
   • Fanning of spinous processes suggests posterior ligamentous disruption
   • Widening of facet joints
   • Check atlanto-occipital joint
   • Line extending inferiorly from clivus should transect odontoid
   • Atlanto-axial articulation, widening of predental space (normal: < 3 mm in adults, < 5 mm in children) indicates injury of C1 or C2

B Bones
   • Height, width, and shape of each vertebral body
   • Pedicles, facets, and laminae should appear as one – doubling suggests rotation

C Cartilage
   • Intervertebral disc spaces – wedging anteriorly or posteriorly suggests vertebral compression

S Soft Tissues
   • Widening of retropharyngeal (normal: < 7 mm at C1-4, may be wide in children < 2 yr on expiration) or retrotracheal spaces (normal: < 22 mm at C6-T1, < 14 mm in children < 5 yr)

Sequelea of C-Spine Fractures
   • see Neurosurgery, NS32
   • acute phase of SCI
     • spinal shock: absence of all voluntary and reflex activity below level of injury
       • decreased reflexes, no sensation, flaccid paralysis below level of injury, lasting days to months
     • neurogenic shock: loss of vasomotor tone, SNS tone
       • watch for: hypotension (lacking SNS), bradycardia (unopposed PNS), poikilothermia (lacking SNS so no shunting of blood from extremities to core)
       • occurs within 30 min of SCI at level T6 or above, lasting up to 6 wk
       • provide airway support, fluids, atropine (for bradycardia), vasopressors for BP support
   • chronic phase of SCI
     • autonomic dysreflexia: in patients with an SCI at level T6 or above
       • signs and symptoms: pounding headache, nasal congestion, feeling of apprehension or anxiety, visual changes, dangerously increased sBP and dBP
       • common triggers
         – GU causes: bladder distention, urinary tract infection, and kidney stones
         – GI causes: fecal impaction or bowel distension
       • treatment: monitoring and controlling BP, prior to addressing causative issue

Chest Trauma

   • two types: those found and managed in 1º survey and those found and managed in 2º survey

Table 7. Life-Threatening Chest Injuries Found in 1º Survey

Always maintain a high index of suspicion. Do not explore penetrating neck wounds except in the OR. Management: Injuries deep to platysma require further evaluation by angiography, contrast CT, or surgery. If penetrating neck trauma present, don’t:

- Clamp structures (can damage nerves)
- Probe
- Insert NG tube (leads to bleeding)
- Remove weapon/impaled object

Other Potentially Life-Threatening Injuries Related to the Chest

Penetrating Neck Trauma
- Includes all penetrating trauma to the three zones of the neck
- Management: Injuries deep to platysma require further evaluation by angiography, contrast CT, or surgery
- Do not explore penetrating neck wounds except in the OR

Airway Injuries
- Always maintain a high index of suspicion

If Penetrating Neck Trauma Present, DON’T:
- Clamp structures (can damage nerves)
- Probe
- Insert NG tube (leads to bleeding)
- Remove weapon/impaled object

Other Potentially Life-Threatening Injuries Related to the Chest
• larynx
  ▪ history: strangulation, direct blow, blunt trauma, any penetrating injury involving platysma
  ▪ triad: hoarseness, subcutaneous emphysema, palpable fracture, crepitus
  ▪ other symptoms: hemoptysis, dyspnea, dysphonia
  ▪ investigations: CXR, CT scan, arteriography (if penetrating)
  ▪ management
    • airway: manage early because of edema
    • C-spine may also be injured, consider mechanism of injury
    • surgical: tracheotomy vs. repair

• trachea/bronchus
  ▪ frequently missed
  ▪ history: deceleration, penetration, increased intra-thoracic pressure, complaints of dyspnea, hemoptysis
  ▪ examination: subcutaneous air, Hamman’s sign (crunching sound synchronous with heart beat)
  ▪ CXR: mediastinal air, persistent pneumothorax or persistent air leak after chest tube inserted for pneumothorax
  ▪ management: surgical repair if >1/3 circumference

Abdominal Trauma

• two mechanisms
  ▪ blunt: usually causes solid organ injury (spleen = most common, liver = 2nd)
  ▪ penetrating: usually causes hollow organ injury or liver injury (most common)

BLUNT TRAUMA
• results in two types of hemorrhage: intra-abdominal and retroperitoneal
• adopt high clinical suspicion of bleeding in multi-system trauma

History
• mechanism of injury, SAMPLE history

Physical Exam
• often unreliable in multi-system trauma, wide spectrum of presentations
  ▪ slow blood loss not immediately apparent
  ▪ other injuries may mask symptoms
  ▪ serial examinations are required
• abdomen
  ▪ inspect: contusions, abrasions, seatbelt sign, distention
  ▪ auscultate: bruits, bowel sounds
  ▪ palpate: tenderness, rebound tenderness, rigidity, guarding
  ▪ DRE: rectal tone, blood, bone fragments, prostate location
  ▪ placement of NG, Foley catheter should be considered part of the abdominal exam
• other systems to assess: cardiovascular, respiratory (possibility of diaphragm rupture), genitourinary, pelvis, back/neurological

Investigations
• labs: CBC, electrolytes, coagulation, cross and type, glucose, Cr, CK, lipase, amylase, liver enzymes, ABG, blood EtOH, β-hCG, U/A, toxicology screen

</table>
| CT Scan                 | Most specific test                                                        | Radiation exposure 20x more than x-ray
                                                | Cannot use if hemodynamic instability            |
| Diagnostic Peritoneal   | Most sensitive test Tests for intra-peritoneal bleed                       | Cannot test for retroperitoneal bleed or diaphragmatic rupture
                                                | Cannot distinguish lethal from trivial bleed    |
| Lavage (rarely used)    |                                                                           | Results can take up to 1 h                       |
| U/S: FAST               | Identifies presence/absence of free fluid in peritoneal cavity RAPID exam: less than 5 min Can also examine pericardium and pleural cavities | NOT used to identify specific organ injuries
                                                | If patient has ascites, FAST will be falsely positive |

Seatbelt Injuries may Cause:
• Retropertioneal duodenal trauma
• Intraperitoneal bowel transection
• Meenteric injury
• L-spine injury

Indications for Foley and NG Tube in Abdominal Trauma
Foley catheter: unconscious or patient with multiple injuries who cannot void spontaneously
NG tube: used to decompress the stomach and proximal small bowel

Criteria for Positive Lavage
• >10 cc gross blood
• Bile, bacteria, foreign material
• RBC count >100,000 x 10^6/L
• WBC > 500 x 10^6/L
• Amylase >175 IU
• imaging must be done if
  ▪ equivocal abdominal examination, altered sensorium, or distracting injuries (e.g. head trauma, spinal cord injury resulting in abdominal anesthesia)
  ▪ unexplained shock/hypotension
  ▪ multiple trauma patients who must undergo general anesthesia for orthopedic, neurosurgical, or other injuries
  ▪ fractures of lower ribs, pelvis, spine
  ▪ positive FAST

Management
• general: ABCs, fluid resuscitation, and stabilization
• surgical: watchful waiting vs. laparotomy
• solid organ injuries: decision based on hemodynamic stability, not the specific injuries
• hemodynamically unstable or persistently high transfusion requirements: laparotomy
• hollow organ injuries: laparotomy
• even if low suspicion of injury: admit and observe for 24 h

PENETRATING TRAUMA
• high risk of gastrointestinal perforation and sepsis
• history: size of blade, caliber/distance from gun, route of entry
• local wound exploration under direct vision may determine lack of peritoneal penetration (not reliable in inexperienced hands) with the following exceptions:
  ▪ thoracoabdominal region (may cause pneumothorax)
  ▪ back or flanks (muscles too thick)

Management
• general: ABCs, fluid resuscitation, and stabilization
• gunshot wounds → always require laparotomy

Genitourinary Tract Injuries
• see Urology, U31

Etiology
• blunt trauma: often associated with pelvic fractures
  ▪ upper tract
    ▪ renal
      ▪ contusions (minor injury – parenchymal ecchymoses with intact renal capsule)
      ▪ parenchymal tears/laceration: non-communicating (hematoma) vs. communicating (urine extravasation, hematuria)
    ▪ ureter: rare, at uretero-pelvic junction
  ▪ lower tract
    ▪ bladder
      ▪ extraperitoneal rupture of bladder from pelvic fracture fragments
      ▪ intraperitoneal rupture of bladder from trauma and full bladder
    ▪ urethra
      ▪ posterior urethral injuries: MVCs, falls, pelvic fractures
      ▪ anterior urethral injuries: blunt trauma to perineum, straddle injuries/direct strikes
  ▪ external genitalia
• penetrating trauma
  ▪ damage to: kidney, bladder, ureter (rare), external genitalia
• acceleration/deceleration injury
  ▪ renal pedicle injury: high mortality rate (laceration and thrombosis of renal artery, renal vein, and their branches)
• iatrogenic
  ▪ ureter and urethra (from instrumentation)

History
• mechanism of injury
• hematuria (microscopic or gross), blood on underwear
• dysuria, urinary retention
• history of hypotension
Physical Exam
- abdominal pain, flank pain, CVA tenderness, upper quadrant mass, perineal lacerations
- DRE: sphincter tone, position of prostate, presence of blood
- scrotum: ecchymoses, lacerations, testicular disruption, hematomas
- bimanual exam, speculum exam
- extraperitoneal bladder rupture: pelvic instability, suprapubic tenderness from mass of urine or extravasated blood
- intraperitoneal bladder rupture: acute abdomen
- urethral injury: perineal ecchymosis, scrotal hematoma, blood at penile meatus, high riding prostate, pelvic fractures

Investigations
- urethra: retrograde urethrography
- bladder: U/A, CT scan, urethrogram ± retrograde cystoscopy, ± cystogram (distended bladder + post-void)
- ureter: retrograde ureterogram
- renal: CT scan (best, if hemodynamically stable), intravenous pyelogram

Management
- urology consult
- renal
  - minor injuries: conservative management
    - bedrest, hydration, analgesia, antibiotics
  - major injuries: admit
    - conservative management with frequent reassessments, serial U/A ± re-imaging
    - surgical repair (exploration, nephrectomy): hemodynamically unstable or continuing to bleed >48 h, major urine extravasation, renal pedicle injury, all penetrating wounds and major lacerations, infections, renal artery thrombosis
- ureter
- ureterourethostomy
- bladder
  - extraperitoneal
    - minor rupture: Foley drainage x 10-14 d
    - major rupture: surgical repair
  - intraperitoneal
    - drain abdomen and surgical repair
- urethra
  - anterior: conservative, if cannot void → Foley or suprapubic cystostomy and antibiotics
  - posterior: suprapubic cystostomy (avoid catheterization) ± surgical repair

Orthopedic Injuries
- see Orthopedics (Shoulder OR11, Knee OR30, Wrist OR20, Ankle OR36)

Goals of ED Treatment
- diagnose potentially life/limb threatening injuries
- reduce and immobilize fractures (cast/splint) as appropriate
- provide adequate pain relief
- arrange proper follow-up if necessary

History
- use SAMPLE
- mechanism of injury may be very important

Physical Exam
- look (inspection): “SEADS” Swelling, Erythema, Atrophy, Deformity, Skin changes (e.g. bruises)
- feel (palpation): all joints/bones for local tenderness, swelling, warmth, crepitus, joint effusions, subtle deformity
- move: joints affected plus those above and below injury – active ROM preferred to passive
- neurovascular status: distal to injury (before and after reduction)
LIFE- AND LIMB-THREATENING INJURIES

Table 10. Life- and Limb-Threatening Orthopedic Injuries

<table>
<thead>
<tr>
<th>Life-Threatening Injuries (usually blood loss)</th>
<th>Limb-Threatening Injuries (usually interruption of blood supply)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Major pelvic fractures</td>
<td>Fracture/dislocation of ankle (talar AVN)</td>
</tr>
<tr>

<td>Open fractures</td>
</tr>
<tr>
<td></td>
<td>Dislocations of knee/hip</td>
</tr>
<tr>
<td></td>
<td>Fractures above knee/elbow</td>
</tr>
</tbody>
</table>

Open Fractures
- communication between fracture site and external surface of skin – increased risk of osteomyelitis
- remove gross debris, irrigate, cover with sterile dressing – formal irrigation and debridement often done in the OR
- control bleeding with pressure (no clamping)
- splint
- antibiotics (1st generation cephalosporin and aminoglycoside) and tetanus prophylaxis
- must secure definitive surgical care within 6-8 h

Vascular Injuries
- realign limb/apply longitudinal traction and reassess pulses (e.g. Doppler probe)
- surgical consult
- direct pressure if external bleeding

Compartment Syndrome
- increased interstitial pressure in an anatomical “compartment” (forearm, calf) with little room for expansion, resulting in decreased perfusion and potential muscle/nerve necrosis
- clinical diagnosis: maintain a high index of suspicion
  - pain out of proportion to the injury
  - pain worse with passive stretch
  - look for “the 6 Ps”
- requires prompt decompression: remove constrictive casts, dressings; fasciotomy may be needed emergently

UPPER EXTREMITY INJURIES
- anterior shoulder dislocation
  - axillary nerve (lateral aspect of shoulder) and musculocutaneous nerve (extensor aspect of forearm) at risk
  - seen on lateral view: humeral head anterior to glenoid
    - reduce (traction, scapular manipulation), immobilize in internal rotation, repeat x-ray, out-patient follow-up with orthopedics
    - with forceful injury, look for fracture
- Colles’ fracture
  - distal radius fracture with dorsal displacement from “Fall on Outstretched Hand” (FOOSH)
  - AP film: shortening, radial deviation, radial displacement
  - lateral film: dorsal displacement, volar angulation
  - reduce, immobilize with splint, out-patient follow-up with orthopedics or immediate orthopedics referral if complicated fracture
  - if involvement of articular surface, emergent orthopedic referral
  - scaphoid fracture
    - tenderness in anatomical snuff box, pain on scaphoid tubercle, pain on axial loading of thumb
    - negative x-ray: thumb spica splint, repeat x-ray in 1 wk ± bone scan
    - positive x-ray: thumb spica splint x 6-8 wk, repeat x-ray in 2 wk
    - risk of AVN of scaphoid if not immobilized
    - outpatient orthopedic follow-up

LOWER EXTREMITY INJURIES
- ankle and foot fractures
  - see Ottawa Ankle and Foot Rules
- knee injuries
  - see Ottawa Knee Rules
• avulsion of the base of 5th metatarsal
  ▪ occurs with inversion injury
  ▪ supportive tensor or below knee walking cast for 3 wk

• calcaneal fracture
  ▪ associated with fall from height
  ▪ associated injuries may involve ankles, knees, hips, pelvis, lumbar spin

A knee x-ray examination is required only for acute injury patients with one or more of:

• Age 55 yr or older
• Tenderness at head of fibula
• Isolated tenderness of patella
• Inability to flex to 90º
• Inability to bear weight both immediately and in ED (four steps)

Wound Management

Goals of ED Treatment

• identify injuries and stop any active bleeding – direct pressure
• manage pain
• wound examination and exploration (history and physical)
• cleansing ± antibiotic and tetanus prophylaxis
• closure and dressing

Tetanus Prophylaxis

• both tetanus toxoid (Td) and immunoglobulin (TIG) are safe in pregnancy

Table 11. Guidelines for Tetanus Prophylaxis for Wounds

¹ wounds >6 h old, >1 cm deep, puncture wounds, avulsions, wounds resulting from missiles, crush wounds, burns, frostbite, wounds contaminated with dirt, feces, soil, or saliva

² 0.5 mL IM tetanus and diphtheria toxoids (Td), adsorbed
³ tetanus immune globulin (TIG), 250 units deep IM

Accuracy of Ottawa Ankle Rules to Exclude Fractures of the Ankle and Mid-Foot: Systematic Review

This systematic review and meta-analysis of 27 studies including 15,561 patients evaluated the sensitivity and specificity of the Ottawa Ankle Rules for excluding fractures of the ankle and mid-foot.

Results: The pooled likelihood ratio of a negative result (obtaining a false negative) among those with a fracture was determined to be 0.08 for both the ankle and mid-foot.

Conclusions: The Ottawa Ankle Rules provide an accurate instrument for excluding fractures of the ankle and mid-foot with a sensitivity of almost 100% and a specificity of 26%. The use of this instrument can reduce the number of unnecessary radiographs.
Brises
• non-palpable = ecchymosis
• palpable collection (not swelling) = hematoma following blunt trauma
• assess for coagulopathy (e.g. liver disease), anticoagulant use

Abrasions
• partial to full thickness break in skin
• management
  ▪ clean thoroughly with brush to prevent foreign body impregnation ± local anesthetic
  ▪ antiseptic ointment (Polysporin® or Vaseline®) for 7 d for facial and complex abrasions
  ▪ tetanus prophylaxis

Lacerations
• see Plastic Surgery, PL8
• consider every structure deep to a laceration injured until proven otherwise
• in hand injury patients, include the following in history: handedness, occupation, mechanism of injury, previous history of injury
• physical exam
  ▪ think about underlying anatomy
  ▪ examine tendon function actively against resistance and neurovascular status distally
  ▪ clean and explore under local anesthetic; look for partial tendon injuries
• management
  ▪ disinfect skin/use sterile techniques
  ▪ irrigate copiously with NS
  ▪ analgesia ± anesthesia
  ▪ maximum dose of lidocaine:
    ▪ 7 mg/kg with epinephrine
    ▪ 5 mg/kg without epinephrine
• in children, topical anesthetics such as LET (lidocaine, epinephrine and tetracaine), and in selected cases a short-acting benzodiazepine (midazolam or other agents) for sedation and amnesia are useful
• secure hemostasis
• evacuate hematomas, debride non-viable tissue, remove hair and foreign bodies
• ± prophylactic antibiotics (consider for animal/human bites, intraoral lesion, or puncture wounds to the foot)
• suture unless: delayed presentation (>6-8 h), puncture wound, mammalian bite, crush injury, or retained foreign body
  ▪ take into account patient and wound factors when considering suturing
• advise patient when to have sutures removed
• cellulitis and necrotising fasciitis, see Plastic Surgery, PL14

Approach to Common ED Presentations

Abdominal Pain

Rule Out Life-Threatening Causes
• CVS: MI, aortic dissection (tearing pain), ruptured AAA
• GI: perforated viscus, hepatic/splenic injury, ischemic bowel (diffuse pain), strangulated hernia
• gynecologic: ectopic pregnancy

Additional Differential Diagnosis
• GI: appendicitis, diverticulitis, bowel obstruction, hepatitis, cholecystitis, pancreatitis
• urinary: pyelonephritis, ureteral calculi, cystitis
• genital
  ▪ female: tubo-ovarian abscess, ovarian torsion, ovarian cyst, salpingitis, PID, endometriosis
  ▪ male: testicular torsion, epididymitis, prostatitis
• other: DKA, herpes zoster virus, intra-abdominal abscess, pneumonia, lead poisoning, porphyria, sickle cell crisis, acute angle closure glaucoma, Addison’s crisis, psychiatric

History
• pain: OPQRST
• broad differential, including GU, gynecological, GI, respiratory, and CV systems
• recent/remote abdominal trauma/surgeries
• most recent colonoscopy

Alternatives to Sutures
• tissue glue
• Steristrips®
• staples

Where NOT to use local anesthetic with epinephrine:
• ears, nose, fingers, toes, and penis

High Risk Factors for Infection

Wound Factors
• puncture wounds
• crush injuries
• wounds >12 h old
• hand or foot wounds
• immunocompromised

Patient Factors
• age >50 yr
• prosthetic joints or valves (risk of endocarditis)

Early wound irrigation and debridement are the most important factors in decreasing infection risk

Be vigilant in those at extremes of ages (very young, elderly) as they often present atypically

Old age, pregnancy (T3), and chronic corticosteroid use can blunt peritoneal findings, so have an increased suspicion of intra-abdominal process in these individuals

If elevated AST and ALT:
think hepatocellular injury
AST > ALT: alcohol-related
ALT > AST: viral, drug, toxin
If elevated ALP and GGT:
think biliary tree stones
Physical Exam
- vitals, abdominal (including DRE, CVA tenderness), pelvic/genital, respiratory, and CVS as indicated by history

Investigations
- do not delay consultation if patient unstable
- CBC, electrolytes, glucose, BUN/Cr, U/A ± LFTs, lipase, β-hCG, ECG, troponins
- AXR: look for calcifications, free air, gas pattern, air fluid levels
- CXR upright: look for pneumoperitoneum (free air under diaphragm)
- U/S: biliary tract, ectopic pregnancy, AAA, free fluid
- CT: trauma, AAA, pancreatitis, nephro/uroolithiasis, appendicitis, and diverticulitis

Management
- NPO, IV, NG tube, analgesics, consider antibiotics and anti-emetics
- growing evidence that small amounts of opioid analgesics improve diagnostic accuracy of physical exam of surgical abdomen
- consult as necessary: general surgery, vascular surgery, gynecology, etc.

Disposition
- admission: surgical abdomen, workup of significant abnormal findings, need for IV antibiotics or pain control
- discharge: patients with a negative lab and imaging workup who improve clinically during their stay; instruct the patient to return if severe pain, fever, or persistent vomiting develop

Acute Pelvic Pain

Etiology
- gynecological
  - ovaries: ruptured ovarian cysts (most common cause of pelvic pain), ovarian abscess, ovarian torsion (rare, 50% will have ovarian mass)
  - fallopian tubes: salpingitis, tubal abscess, hydrosalpinx
  - uterus: leiomyomas (uterine fibroids) – especially with torsion of a pedunculated fibroid or in pregnant patient (degeneration), PID, endometriosis
  - other: ectopic pregnancy (ruptured/expanding/leaking), spontaneous abortion (threatened or incomplete), endometriosis and dysmenorrhea, sexual, or physical abuse
- non-gynecological
  - GI: appendicitis, constipation, bowel obstruction, gastroenteritis, diverticulitis, IBD, IBS
  - GU: cystitis, pyelonephritis, ureteric stone
  - other: porphyria, abdominal angina, aneurysm, hernia, zoster, psychological abuse/domestic violence

History and Physical Exam
- pain: OPQRST
- associated symptoms: vaginal bleeding, bowel or bladder symptoms, radiation
- vitals
- gynecological exam: assess for cervical motion tenderness/“chandelier sign” (suggests PID)
- abdominal exam

Investigations
- blood work
  - β-hCG for all women of childbearing age
- CBC and differential, electrolytes, glucose, BUN/Cr, G&S, PTT/INR
- imaging
  - pelvic and abdominal U/S: evaluate adnexa, look for free fluid or masses in the pelvis, evaluate thickness of endometrium, confirm intrauterine pregnancy if β-hCG positive
- doppler flow studies for ovarian torsion

Management
- general: analgesia, determine if admission and consults are needed
- specific
  - ovarian cysts
    - unruptured or ruptured and hemodynamically stable: analgesia and follow-up
    - ruptured with significant hemoperitoneum: may require surgery
  - ovarian torsion: surgical detorsion or removal of ovary
  - uncomplicated leiomyomas, endometriosis, and secondary dysmenorrhea can usually be treated on an outpatient basis, discharge with gynecology follow-up
  - PID: requires broad spectrum antibiotics
Disposition
• referral: gynecological or obstetrical causes requiring surgical intervention, requiring admission, or oncological in nature
• admission: patients requiring surgery, IV antibiotics/pain management
• discharge: negative workup and resolving symptoms; give clear instructions for appropriate follow-up

Altered Level of Consciousness

Definitions
• altered mental status: collective, non-specific term referring to change in cognitive function, behavior, or attentiveness, including:
  ▪ delirium (see Psychiatry, PS16)
  ▪ dementia (see Psychiatry, PS17)
  ▪ lethargy: state of decreased awareness and alertness (patient may appear wakeful)
  ▪ stupor: unresponsive but arousable
  ▪ coma: a sleep-like state, not arousable to consciousness
• use the GCS to evaluate LOC (see Initial Patient Assessment/Management, ER2)

Figure 11. Etiology of coma

MANAGEMENT OF ALTERED LOC

History
• obtain collateral from family, friends, police, paramedics, old chart, etc.
• onset and progression
  ▪ abrupt onset suggests CNS hemorrhage/ischemia or cardiac cause
  ▪ progression over hours to days suggests progressive CNS lesion or toxic/metabolic cause
• preceding events
  ▪ it is essential to determine patient’s baseline LOC
  ▪ antecedent trauma, seizure activity, fever
  ▪ past medical history (e.g. similar episode, depression, overdose)

Physical Exam
• ABCs, vitals including temperature, cardiac, chest, respiratory, abdominal exam
• complete neuro exam, in particular examination of the eyes (pupil size and reactivity), look for MedicAlert* bracelet

Investigations
• blood work
  ▪ rapid blood sugar, CBC, electrolytes, Cr, BUN, LFTs, glucose, serum osmolality, VBG, PT/PTT/INR, troponins
  ▪ serum EtOH, acetaminophen, and salicylate levels
• imaging
  ▪ CXR, CT head
• other tests
  ▪ ECG, U/A, UTox
Diagnosis
- administer appropriate universal antidotes
  - thiamine 100 mg IV if history of EtOH or patient looks malnourished
  - one ampule D50W IV if low blood sugar on finger-prick
  - naloxone 0.4-2 mg IV or IM if opiate overdose suspected
- distinguish between structural and toxic-metabolic coma
  - structural coma
    - pupils, extraocular movements, and motor findings, if present, are usually asymmetric
    - look for focal or lateralizing abnormalities
  - toxic-metabolic coma
    - dysfunction at lower levels of the brainstem (e.g. caloric unresponsiveness)
    - respiratory depression in association with an intact upper brainstem (e.g. equal and reactive pupils; see exceptions in Table 12)
    - extraocular movements and motor findings are symmetric or absent
- essential to re-examine frequently because status can change rapidly
- diagnosis may become apparent only with the passage of time
  - delayed deficit after head trauma suggestive of epidural hematoma (characteristic "lucid interval")

</tbody>
</table>

Disposition
- admission: if ongoing decreased LOC, admit to service based on tentative diagnosis, or transfer patient if appropriate level of care not available
- discharge: readily reversible alteration of LOC; ensure adequate follow-up care available

Chest Pain

Rule Out Life-Threatening Causes
- CVS: ACS, pericarditis, cardiac tamponade, aortic dissection
- respiratory: PE, pneumothorax (tension or spontaneous)
- GI: esophageal rupture, pneumomediastinum

Additional Differential Diagnosis
- cardiac: stable angina
- respiratory: pneumonia
- GI: peptic ulcer disease, pancreatitis, cholecystitis, esophagitis, reflux, esophageal spasm
- MSK: rib fractures, costochondritis, zoster, etc.
- psychogenic/anxiety (diagnosis of exclusion)

Initial Resuscitation and Management
- O2, IV, cardiac monitoring, CXR (portable if unstable), ECG

History
- must evaluate cardiac risk factors (see TIMI Score, Cardiology and Cardiac Surgery, C27)
  - classic presentations (but presentation seldom classic)
    - aortic dissection: syncope with sudden severe tearing pain, often radiating to back ± focal pain/neuroligic loss in extremities secondary to major vessel ischemia
    - PE: pleuritic chest pain (75%), dyspnea, anxiety, tachycardia, PERC Score
    - pericarditis: anterior precordial pain, pleuritic, relieved by sitting up and leaning forward
    - ACS: retrosternal squeezing/pressure pain, radiation to arm/neck, dyspnea, N/V, syncope
    - esophageal: frequent heartburn, acid reflex, dysphagia, relief with antacids
  - ACS more likely to be atypical in females, diabetics, and >80 yr

Physical Exam
- vitals (BP in both arms, but unreliable indicator of dissection)
- palpate chest wall for tender points; present in 25% of acute MI, but may suggest MSK cause if symptoms fully reproduced and all serious etiologies have been ruled out
- cardiac, respiratory, and peripheral vascular exams

</table>
ACUTE MYOCARDIAL INFARCTION
• see Cardiology and Cardiac Surgery, C27

Management
• immediate stabilization
  ▪ oxygen 4 L/min
  ▪ IV access
  ▪ cardiac monitors
  ▪ STAT ECG
  ▪ cardiac enzymes (CK, troponins)
• ASA 162-325 mg chewed
• nitroglycerin 0.3 mg SL q5min x 3 (IV for CHF, HTN, unresolved pain)
  ▪ do not use if patient is hypotensive or in the setting of an inferior MI
• morphine 2-5 mg IV q5-30min if unresponsive to nitroglycerin
  ▪ do not use if patient is hypotensive or in the setting of an inferior MI
• low molecular weight heparin 1 mg/kg SC bid (30 mg IV STAT post TNK/tenecteplase infusion)
• thrombolytics (within 30 min) or primary percutaneous coronary intervention (within 90 min)
  ▪ agents include rt-PA, streptokinase, and TNK
  ▪ evaluate indications and contraindications prior to use
• other: antidysrhythmics, cardioversion, defibrillation, transthoracic pacing, angioplasty
• cardiology consult

Epistaxis
• see Otolaryngology, OT27
• 90% of nosebleeds stem from the anterior nasal septum (at Kieselbach’s plexus located in Little’s area)
• can be life-threatening

Etiology
• most commonly caused by trauma (digital, blunt, foreign bodies)
• other causes: barometric changes, nasal dryness, chemicals (cocaine, Otrivin†), or systemic disease (coagulopathies, HTN, etc.)

Investigations
• blood work: CBC, PT/PTT (as indicated)
• imaging: x-ray, CT as needed

Treatment
• aim is to localize bleeding and achieve hemostasis
• first-aid: ABCs, clear clots by blowing nose or suctioning, lean forward, pinch cartilaginous portion of nose for 20 min twice
• assess blood loss: vitals, IV NS, cross match 2 units pRBC if significant
• if first aid measures fail twice, proceed to packing
• apply an anterior pack
  ▪ clear nose of any clots
  ▪ apply topical anesthesia/vasoconstrictors (lidocaine with epinephrine, cocaine, or soaked pledgets)
  ▪ insert either a traditional Vaseline† gauze pack or a commercial nasal tampon or balloon
  ▪ if bleeding stops, arrange follow-up in 48-72 h for reassessment and pack removal
  ▪ prophylactic anti-staphylococcal antibiotics should be prescribed to prevent sinusitis or toxic shock syndrome
  ▪ if bleeding is controlled with anterior pressure, cautery with silver nitrate can be performed
    ▪ if the site of bleeding is identified (one side of septum only because if both are cauterized this can lead to septal perforation)
  ▪ if suspect posterior bleed or anterior packing does not provide hemostasis, consult ENT for posterior packing and further evaluation
• posterior packing (ENT consult)
  ▪ posterior packing requires monitoring because can cause significant vagal response and posterior bleeding source can lead to significant blood loss

Disposition
• discharge: discharged upon stabilization and appropriate follow-up; educate patients about prevention (e.g. humidifiers, saline spray, topical ointments, avoiding irritants, managing HTN)
• admission: severe cases of refractory bleeding
Headache

- see Neurology, N43

Etiology

- the common
  - common migraine (no aura)/classic migraine (with aura)
    - gradual onset, unilateral/bilateral, throbbing
    - N/V, photo/phonophobia
    - treatment: analgesics, antiepileptic drugs, vasoactive medications
  - tension/muscular headache
    - never during sleep, gradual over 24 h
    - posterior/occipital
    - increased with stressors
    - treatment: modify stressor(s), local measures, NSAIDs, tricyclic antidepressants

- the deadly
  - SAH (see Neurosurgery, NS18)
    - sudden onset, increased with exertion
    - reaches maximum intensity within minutes, N/V, meningeal signs
    - diagnosis: CT, LP (5-10% of patients with SAH have negative initial CT)
      - sensitivity of CT decreases with time and is much less sensitive by 48-72 h
    - management: urgent neurosurgery consult
  - increased ICP
    - worse in morning, when supine or bending down, with cough or Valsalva
    - physical exam: neurological deficits, cranial nerve palsies, papilledema
    - diagnosis: CT scan
    - management: consult neurosurgery
  - meningitis (see Infectious Diseases, ID19)
    - flu-like presentation initially (fever, N/V, malaise), meningeal signs, purpuric rash
    - altered LOC and confusion
    - perform CT to rule out increased ICP then do LP for diagnosis
    - treatment: early empiric antibiotics (depending on age group), steroid therapy
  - temporal arteritis (causes significant morbidity, blindness) (see Ophthalmology, OP38)
    - unilateral scalp tenderness, jaw claudication, visual disturbances
    - labs: elevated ESR, CRP
    - temporal artery biopsy is gold standard for diagnosis
    - associated with polymyalgia rheumatica
    - treatment: high-dose steroids immediately if suspected

Disposition

- admission: if underlying diagnosis is critical or emergent, if there are abnormal neurological findings, if patient is elderly or immunocompromised (atypical presentation), or if pain is refractory to oral medications
- discharge: assess for risk of narcotic misuse, most patients can be discharged with appropriate analgesia and follow-up with their family physician; instruct patients to return for fever, vomiting, neurologic changes, or increasing pain

Joint Pain

- see Rheumatology, RH3

Rule Out Life-Threatening Causes

- septic joint (see Orthopedics, OR10)

Differential Diagnosis

- articular pain
  - monoarticular
    - infectious: bacterial, viral, fungal
    - hemarthrosis: trauma/fracture, anticoagulants, bleeding diatheses
    - crystal induced: gout, calcium pyrophosphate deposition, hydroxyapatite
    - inflammatory: seropositive, seronegative
    - neoplasm
    - degenerative: osteoarthritis
  - polyarticular
    - infectious: Lyme disease, bacterial endocarditis, septicemia, gonococcus, viral
    - post-infectious: rheumatic fever, reactive arthritis, enteric infections
    - inflammatory: seropositive, seronegative
    - degenerative: osteoarthritis

Dexamethasone for Reduction of Migraine Recurrence

Shows that a single dose of IV dexamethasone may decrease recurrence of migraine within 24 h [NNT 10].

Note: up to 5% of patients with SAH have a normal CT scan; if suspect SAH with a negative CT, perform a LP

DDx Subarachnoid Hemorrhage

BATS
Berry aneurysm
Arteriovenous malformation
Adult polycystic kidney disease
Trauma
Stroke

Meningitis

- Do not delay IV antibiotics for LP
- Deliver 1st dose of dexamethasone with or before 1st doses of antibiotic therapy

Ottawa SAH Rules

- For alert patients older than 15 yr with new severe non-traumatic headache reaching maximum intensity within 1 h
- Not for patients with new neurologic deficits, previous aneurysms, SAH, brain tumors, or history of recurrent headaches (≥3 episodes over the course of ≥6 mo)
- Investigate if ≥1 high-risk variables present:
  - Age ≥40 yr
  - Neck pain or stiffness
  - Witnessed loss of consciousness
  - Onset during exertion
  - Thunderclap headache (instantly peaking pain)
  - Limited neck flexion on examination
• non-articular
  ▪ localized: tendinitis, bursitis, capsulitis, muscle sprain
  ▪ generalized: fibromyalgia, polymyalgia rheumatica
• other
  ▪ neurologic: spinal stenosis/spondylolisthesis, degenerative disc disease, cauda equina syndrome, neoplasm, thoracic outlet syndrome, Charcot joint
  ▪ vascular: intermittent claudication

History and Physical Exam
• associated symptoms: fever, constitutional symptoms, skin lesions, conjunctivitis, urethritis
• patterns of joint involvement: polyarticular vs. monoarticular, symmetric vs. asymmetric
• inflammatory symptoms: prolonged morning stiffness, stiffness and pain ease through the day, midday fatigue, soft tissue swelling
• non-inflammatory symptoms: stiffness short lived after inactivity, short duration stiffness in the morning, pain increases with activity
• assess ROM, presence of joint effusion, warmth
• assess for localized joint pain, erythema, warmth, swelling with pain on active ROM, inability to bear weight, fever; may indicate presence of septic joint

Investigations
• blood work
  ▪ CBC, ESR, CRP, WBC, INR/PTT, blood cultures, urate
• imaging
  ▪ joint x-ray ± contralateral joint for comparison
• other investigations
  ▪ joint aspirate → send for: WBC, protein, glucose, Gram stain, crystals

Management
• septic joint: IV antibiotics ± joint decompression and drainage
  ▪ antibiotics can be started empirically if septic arthritis cannot be ruled out
• crystalline synovitis: NSAIDs at high dose, colchicine within first 24 h, corticosteroids
  ▪ do not use allopurinol, as it may worsen acute attack
• acute polyarthritis: NSAIDs, analgesics (acetaminophen ± opioids), local or systemic corticosteroids
• osteoarthritis: NSAIDs, acetaminophen
• soft tissue pain: allow healing with enforced rest ± immobilization
  ▪ non-pharmacologic treatment: local heat or cold, electrical stimulation, massage
  ▪ pharmacologic: oral analgesics, NSAIDs, muscle relaxants, corticosteroid injections, topical agents

Hospitalization is required for joint pain in the presence of:
• Significant, concomitant internal organ involvement
• Signs of bacteremia, including vesiculopustular skin lesions, Roth spots, shaking chills, or splinter hemorrhages
• Systemic vasculitis
• Severe pain
• Severe constitutional symptoms
• Purulent synovial fluid in one or more joints
• Immunosuppression

Otalgia

Differential Diagnosis (see Otolaryngology, OT6)
• local
  ▪ infections: acute otitis externa, acute otitis media, otitis media with effusion, mastoiditis, myringitis, malignant otitis in diabetics, herpes simplex/zoster, auricular cellulitis, external canal abscess, dental disease
  ▪ others: trauma, temporomandibular joint dysfunction, neoplasm, foreign body, cerumen impactions, trigeminal neuralgia, granulomatosis with polyangiitis

History
• OPQRST
• associated symptoms: aural fullness (feeling of pressure), otorrhea, hearing loss, tinnitus, vertigo, pruritis, fever
• risk factors: Q-tip use, hearing aids, headphones

Physical Exam
• observe for otorrhea, palpation of outer ear/mastoid, otoscope to see bulging erythematous tympanic membrane, perforation

Investigations
• consider audiogram if hearing loss
• C&S of ear canal discharge, if present
• CT head if suspicion of mastoiditis, malignant otitis media

Management
• debridement of cerumen or exudates
• antibiotics/antifungals/antivirals for respective infections
Seizures

• see Neurology, N16

Definition
• paroxysmal alteration of behavior and/or EEG changes resulting from abnormal, excessive activity of neurons
• status epilepticus: continuous or intermittent seizure activity for greater than 5 min without regaining consciousness

Categories
• generalized seizure (consciousness always lost): tonic/clonic, absence, myoclonic, atonic
• partial seizure (local): simple partial, complex partial
• causes: primary seizure disorder, structural (trauma, intracranial hemorrhage, infection, increased ICP), metabolic disturbance (hypo/hyperglycemia, hypo/hypernatremia, hypocalcemia, hypomagnesemia, toxins/drugs)
• differential diagnosis: syncope, pseudoseizures, migraines, movement disorders, narcolepsy/cataplexy, myoclonus

History
• from patient and bystander: flaccid and unconscious, often with deep rapid breathing
• preceding aura, rapid onset, loss of bladder/bowel control, tongue-biting (sides of the tongue)
• timing: length of seizure

Physical Exam
• injuries to head and spine and bony prominences (e.g. elbows), tongue laceration, aspiration, urinary incontinence

Investigations
• known seizure disorder: antiepileptic drug levels
• Accu-Chek®
• first time seizure: CBC, serum glucose, electrolytes, BUN/Cr, Ca²⁺, Mg²⁺; consider prolactin, β-hCG, toxicology screen
• initial imaging: CT; x-ray if suspected extremity injuries; definitive imaging: MRI, EEG

Table 14. Management of Status Epilepticus

<table>
<thead>
<tr>
<th>Time (min)</th>
<th>Steps</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-5</td>
<td>Give oxygen; ensure adequate ventilation Monitor: vital signs, ECG, axiometry Establish IV access; obtain blood samples for glucose level, CBC, electrolytes, toxins, and antiepileptic drug levels</td>
</tr>
<tr>
<td>6-9</td>
<td>Give 50 mL 50% glucose (preceded by thiamine 100 mg IM in adults)</td>
</tr>
<tr>
<td>10-20</td>
<td>IV lorazepam 0.1 mg/kg at 2 mg/min or IV diazepam 0.2 mg/kg at 5 mg/min Diazepam can be repeated if seizures do not stop after 5 min; if diazepam is used to stop the status, then phenytoin should be administered promptly to prevent the recurrence of status</td>
</tr>
<tr>
<td>21-60</td>
<td>If status persists, administer 15-20 mg/kg of phenytoin intravenously no faster than 50 mg/min in adults and 1 mg/kg/min in children</td>
</tr>
<tr>
<td>&gt;60</td>
<td>If status does not stop after 20 mg/kg of phenytoin, give additional doses of 5 mg/kg to a maximal dose of 30 mg/kg If status persists, then give 20 mg/kg of phenobarbital IV at 100 mg/min; when phenobarbital is given after a benzodiazepine, ventilatory assistance is usually required If status persists, then give general anesthesia (e.g. pentobarbital); vasopressors or fluid volume are usually necessary, EEG should be monitored; neuromuscular blockade may be needed</td>
</tr>
</tbody>
</table>

Adapted from: Cecil Essentials of Medicine, 7th edition, Table 125-7. Used with permission

Disposition
• the decision to admit or discharge should be based on the underlying disease process identified
  ▶ if a patient has returned to baseline function and is neurologically intact, then consider discharge with outpatient follow-up
• first-time seizure patients being discharged should be referred to a neurologist for follow-up
• admitted patients should generally have a neurology consult
• patient should not drive until medically cleared (local regulations vary)
  ▶ complete notification form to appropriate authority regarding ability to drive
• warn regarding other safety concerns (e.g. no swimming, bathing children alone, etc.)
Shortness of Breath

- see Respirology, R3 and Cardiology and Cardiac Surgery, C5

Etiology
- categorized into one of two groups: respiratory or cardiovascular
- respiratory system dyspnea: disorders of the central controller (brain), the ventilatory pump (ventilatory muscles, peripheral nerves), and the gas exchanger (alveoli and pulmonary capillaries)
- cardiovascular system dyspnea: cardiac diseases (acute ischemia, heart failure, systolic dysfunction, valvular disorders, pericardial diseases, arrhythmias), anemia, and deconditioning

History and Physical Exam
- acute SOB is often due to a relatively limited number of conditions; associated symptoms and signs are key to the appropriate diagnosis
  - substernal chest pain with cardiac ischemia
  - fever, cough, and sputum with respiratory infections
  - urticaria with anaphylaxis
  - wheezing with acute bronchospasm
  - chest tightness may be indicative of bronchospasm
  - a sensation of rapid, shallow breathing may correspond to interstitial disease
  - a sense of heavy breathing is typical of deconditioning
  - ask about environmental or occupational exposures
- dyspnea may be the sole complaint and the physical exam may reveal few abnormalities (e.g. PE, pneumothorax)
- vitals including pulse oximetry
  - wheeze (airway) vs. crackles (parenchymal), JVP, and murmurs

Investigations
- blood work
  - CBC and differential (hematocrit to exclude anemia), electrolytes, consider VBG
  - serial cardiac enzymes and ECG if considering cardiac source
- imaging
  - CXR (hyperinflation and bullous disease suggestive of obstructive lung disease, or changes in interstitial markings consistent with inflammation, infection, or interstitial fluid)
  - CT chest usually is not indicated in the initial evaluation of patients with dyspnea, but can be valuable in patients with interstitial lung disease, occult emphysema, or chronic thromboembolic disease (i.e. PE)

Management of Life-Threatening Dyspnea NYD
- see Primary and Secondary Surveys, ER2, ER5
- treat underlying cause

Disposition
- the history and physical exam lead to accurate diagnoses in patients with dyspnea in approximately two-thirds of cases; the decision to admit or discharge should be based on the underlying disease process identified
  - consider intubation in CO2 retainers (e.g. COPD)
- if the decision to discharge is chosen, provide appropriate discharge instructions to return in case of returning/worsening SOB

Syncope

Definition
- sudden, transient loss of consciousness and postural tone with spontaneous recovery
- usually caused by generalized cerebral or reticular activating system hypoperfusion

Etiology
- cardiogenic: dysrhythmia, outflow obstruction (e.g. PE, tamponade, tension pneumothorax, pulmonary HTN), MI, valvular disease
- non-cardiogenic: peripheral vascular (hypovolemia), vasovagal, cerebrovascular disorders, CNS, metabolic disturbances (e.g. EtOH intoxication)

History
- gather details from witnesses, and clarify patient’s experience (e.g. dizziness, ataxia, or true syncope)
  - two key historical features: prodrome and situation
distinguish between syncope and seizure (see Neurology, N16)
  - some patients may have myoclonic jerks with syncope - NOT a seizure
  - signs and symptoms during presyncope, syncope, and postsyncope
  - past medical history, drugs
  - think anatomically in differential; pump (heart), blood, vessels, brain
  - syncope is cardiogenic until proven otherwise if:
    - there is sudden loss of consciousness with no warning or prodrome
    - syncope is accompanied by chest pain

Physical Exam
- postural BP and HR
- cardiovascular, respiratory, and neurological exam
- physical findings in the elderly patient who falls (I HATE FALLING):
  - Inflammation of joints (or joint deformity)
  - Hypotension (orthostatic BP changes)
  - Auditory and visual abnormalities
  - Tremor (Parkinson’s disease or other causes of tremor)
  - Equilibrium (balance) problem
  - Foot problems
  - Arrhythmia (dysrhythmia), heart block, or valvular disease
  - Leg-length discrepancy
  - Lack of conditioning (generalized weakness)
  - Illness
  - Nutrition (poor; weight loss)
  - Gait disturbance

Investigations
- ECG (tachycardia, bradycardia, blocks, Wolff-Parkinson White, long QT interval), bedside glucose
- blood work: CBC, electrolytes, BUN/Cr, ABGs, troponin, Ca²⁺, Mg²⁺, β-hCG
- consider toxicology screen

Management
- ABCs, IV, O₂, monitor
- examine for signs of trauma caused by syncopal episode
- cardiogenic syncope: admit to medicine/cardiology
- low risk syncope: discharge with follow-up as indicated by cause (non-cardiogenic syncope may still be admitted)

Disposition
- decision to admit is based on etiology
- most patients will be discharged
- on discharge, instruct patient to follow up with family physician
  - educate regarding avoiding orthostatic or situational syncope
  - evaluate the patient for fitness to drive or work
  - patients with recurrent syncope should avoid high-risk activities (e.g. driving)

Sexual Assault

Epidemiology
- 1 in 4 women and 1 in 10 men will be sexually assaulted in their lifetime
- it is estimated that only 7% of rapes are reported

General Approach
- ABCs, treat acute, serious injuries
- ensure patient is not left alone and provide ongoing emotional support
- set aside adequate time for exam (usually 1.5 h)
- obtain consent for medical exam and treatment, collection of evidence, disclosure to police (notify police as soon as consent obtained)
- Sexual Assault Kit (document injuries, collect evidence) if <72 h since assault
- label samples immediately and pass directly to police
- offer community crisis resources (e.g. shelter, hotline)
- do not report unless victim requests (legally required if <16 yr old)

History
- ensure privacy for the patient – others should be asked to leave
- questions to ask: who, when, where did penetration occur, what happened, any weapons or physical assault?
- post-assault activities (urination, defecation, change of clothes, shower, douche, etc.)
- gynecologic history
  - gravidity, parity, last menstrual period
  - contraception use
  - last voluntary intercourse (sperm motile 6-12 h in vagina, 5 d in cervix)
- medical history: acute injury/illness, chronic diseases, psychiatric history, medications, allergies, etc.

**Physical Exam**
- evidence collection is always secondary to treatment of serious injuries
- never re-traumatize a patient with the examination
- general examination
  - mental status
  - sexual maturity
  - patient should remove clothes and place in paper bag
  - document abrasions, bruises, lacerations, torn frenulum/broken teeth (indicates oral penetration)
- pelvic exam and specimen collection
  - ideally before urination or defecation
  - examine for seminal stains, hymen, signs of trauma
  - collect moistened swabs of dried seminal stains
  - pubic hair combings and cuttings
  - speculum exam
    - lubricate with water only
    - vaginal lacerations, foreign bodies
    - Pap smear
    - oral/cervical/rectal culture for gonorrhea and chlamydia
    - posterior fornix secretions if present or aspiration of saline irrigation
    - immediate wet smear for motile sperm
    - air-dried slides for immotile sperm, acid phosphatase, ABO group
- others
  - fingernail scrapings
  - saliva sample from victim

**Investigations**
- VDRL: repeat in 3 mo if negative
- serum β-hCG
- blood for ABO group, Rh type, baseline serology (e.g. hepatitis, HIV)

**Management**
- involve local/regional sexual assault team
- medical
  - suture lacerations
  - tetanus prophylaxis
  - gynecology consult for foreign body, complex lacerations
  - assumed positive for gonorrhea and chlamydia
    - management: azithromycin 1 g PO x 1 dose (alt: doxycycline 100 mg PO bid x 7 d) and cefixime 800 mg PO x 1 dose (alt: ceftriaxone 1 g IM x 1 dose)
  - may start prophylaxis for hepatitis B and HIV
  - pre and post counseling for HIV testing
  - pregnancy prophylaxis offered
    - levonorgestrel 0.75 mg PO STAT, repeat within 12 h (Plan B)
- psychological
  - high incidence of psychological sequelae
  - have victim change and shower after exam completed

**Disposition**
- discharge if injuries/social situation permit
- follow-up with physician in rape crisis center within 24 h
- best if patient does not leave ED alone

**DOMESTIC VIOLENCE**
- women are usually the victims, but male victimization also occurs
- identify the problem (need high index of suspicion)
  - suggestive injuries (bruises, sprains, abrasions, occasionally fractures, burns, or other injuries; often inconsistent with history provided)
  - somatic symptoms (chronic and vague complaints)
  - psychosocial symptoms
  - clinician impression (your ‘gut feeling’, e.g. overbearing partner that won't leave patient's side)
- if disclosed, be supportive and assess danger
- patient must consent to follow-up investigation/reporting (unless for children)
Management

- treat injuries
- ask about sexual assault and children at home (encourage notification of police)
- document findings
- safety plan
- follow-up: family doctor/social worker

Medical Emergencies

Anaphylaxis and Allergic Reactions

Etiology

- anaphylaxis is an exaggerated immune mediated hypersensitivity reaction that leads to systemic histamine release, increased vascular permeability, and vasodilation; regardless of the etiology, the presentation and management of anaphylactic reactions are the same
  - allergic (re-exposure to allergen)
  - non-allergic (e.g. exercise induced)

Presentation

- classic presentation of anaphylaxis includes
  1. rapid onset and progression of symptoms
  2. life-threatening compromise of one or more of airway (breathing/swallowing difficulty, stridor, voice change), breathing (SOB, hypoxemia, wheezing, respiratory arrest), and circulation (tachycardia, hypotension, confusion, decreased urine output, chest pain)
  3. involvement of skin (erythema, urticaria, warmth) and/or mucosa (angioedema, obstruction, GI symptoms) not always present

Management

1. immediate initial management (call for help and perform concurrently)
   - give 0.5 mL of 1:1,000 epinephrine IM to lateral thigh (0.01 mL/kg up to 0.4 mL for children)
   - remove causative agent if possible
   - otherwise, provide 100% O₂ through mask, give bolus 1,000 mL (20 mL/kg for children)
   - have continuous pulse oximetry and telemetry monitoring
   - frequently monitor BP
2. secondary treatment
   - diphenhydramine (Benadryl®) 50 mg IM or IV q4-6h
   - methylprednisolone 50-100 mg IV (dose depending on severity)
   - salbutamol (Ventolin®) via nebulizer if bronchospasm

Disposition

- monitor for 4-6 h in ED (minimum) and arrange follow-up with family physician in 24-48 h
- can have second phase (biphasic) reaction up to 48 h later, patient may need to be supervised (oral steroids on discharge may prevent this)
- educate patient on avoidance of allergens
- 3-day course of:
  - H₁ antagonist (cetirizine 10 mg PO OD or Benadryl® 50 mg PO q4-6h)
  - H₂ antagonist (ranitidine 150 mg PO OD)
  - corticosteroid (prednisone 50 mg PO OD) generally given for 5 d

Asthma

- see Respiriology, R7
- chronic inflammatory airway disease with episodes of bronchospasm and inflammation resulting in reversible airflow obstruction

Investigations

- O₂ saturation
- peak flow meter
- ± ABG if in severe respiratory distress
- CXR if diagnosis in doubt or concerns of pneumonia, pneumothorax, etc.
### Table 15. Asthma Assessment and Management

<table>
<thead>
<tr>
<th>Classifications</th>
<th>History and Physical Exam</th>
<th>Management</th>
</tr>
</thead>
<tbody>
<tr>
<td>Respiratory Arrest</td>
<td>• Exhausted, confused, diaphoretic, cyanotic&lt;br&gt;• Silent chest, ineffective respiratory effort&lt;br&gt;• Decreased HR, RR&gt;30, pCO2&gt;45 mmHg&lt;br&gt;• O2 sat &lt;90% despite supplemental O2</td>
<td>• 100% O2, cardiac monitor, IV access&lt;br&gt;• Intubate (consider induction with ketamine)&lt;br&gt;• β-agonist: nebulizer 5 mg continually&lt;br&gt;• Anticholinergics: nebulizer 0.5 mg x 3&lt;br&gt;• IV steroids: methylprednisolone 125 mg</td>
</tr>
<tr>
<td>Imminent</td>
<td></td>
<td>• Anticipate need for intubation&lt;br&gt;• Similar to above management&lt;br&gt;• Magnesium sulphate 2 g IV&lt;br&gt;• O2 to achieve O2 sat &gt;92%</td>
</tr>
<tr>
<td>Severe Asthma</td>
<td>• Agitated, diaphoretic, labored respirations&lt;br&gt;• Speaking in words&lt;br&gt;• No relief from β-agonist&lt;br&gt;• O2 sat &lt;90%, FEV1 &lt;50%</td>
<td>• β-agonist: MDI or nebulizer q5min&lt;br&gt;• Steroids: prednisone 40-60 mg PO&lt;br&gt;• Anticholinergics (Atrovent) MDI or nebulizer x3</td>
</tr>
<tr>
<td>Moderate Asthma</td>
<td>• SOB at rest, cough, congestion, chest tightness&lt;br&gt;• Speaking in phrases&lt;br&gt;• Inadequate relief from β-agonist&lt;br&gt;• FEV1 50-80%</td>
<td>• O2 to achieve O2 sat &gt;92%&lt;br&gt;• β-agonist: MDI regular use (2-4 puffs q2-4h) until symptoms controlled, then prn&lt;br&gt;• prednisone 30-60 mg/d for 7-14 d with no taper&lt;br&gt;• counsel on medication adherence&lt;br&gt;• inhaled corticosteroids if not already prescribed&lt;br&gt;• follow-up with primary care physician</td>
</tr>
<tr>
<td>Mild Asthma</td>
<td>• Exertional SOB/cough with some nocturnal symptoms&lt;br&gt;• Difficulty finishing sentences&lt;br&gt;• FEV1 &gt;80%</td>
<td>• β-agonist: nebulizer 0.5 mg x 3&lt;br&gt;• Monitor FEV1&lt;br&gt;• Consider steroids (MDI or PO)</td>
</tr>
</tbody>
</table>

### Disposition
- β-agonist MDI regular use (2-4 puffs q2-4h) until symptoms controlled, then prn
- prednisone 30-60 mg/d for 7-14 d with no taper
- counsel on medication adherence
- inhaled corticosteroids if not already prescribed
- follow-up with primary care physician

### Cardiac Dysrhythmias

- see Cardiology and Cardiac Surgery, C15

#### Bradydysrhythmias and AV Conduction Blocks
- AV conduction blocks
  - 1st degree: prolonged PR interval (>200 msec), no treatment required
  - 2nd degree
    - Mobitz I: gradual prolongation of PR interval then dropped QRS complex, usually benign
    - Mobitz II: PR interval constant with dropped QRS complex, can progress to 3rd degree AV block
  - 3rd degree: P wave unrelated to QRS complex, PP and RR intervals constant
    - atropine and transcutaneous pacemaker (atropine with caution)
    - if transcutaneous pacemaker fails consider dopamine, epinephrine IV
    - long-term treatment for Mobitz II and 3rd degree block – internal pacemaker
- sinus bradycardia (rate <60 bpm)
  - can be normal (especially in athletes)
  - causes: vagal stimulation, vomiting, myocardial infarction/ischemia, increased ICP, sick sinus node, hypothyroidism, drugs (e.g. β-blockers, CCBs)
  - treat if symptomatic (hypotension, chest pain)
    - acute: atropine ± transcutaneous pacing
    - sick sinus: transcutaneous pacing
    - drug induced: discontinue/reduce offending drug

#### Supraventricular Tachydysrhythmias (narrow QRS)
- sinus tachycardia (rate >100 bpm)
  - causes: increased sympathetic tone, drugs, fever, hypotension, anemia, thyrotoxicosis, MI, PE, emotional, pain, etc.
  - search for and treat underlying cause, consider β-blocker if symptomatic
- regular rhythm
  - vagal maneuvers (carotid massage, Valsalva), adenosine 6 mg IV push, if no conversion give 12 mg, can repeat 12 mg dose once
  - rhythm converts: probable re-entry tachycardia (AVNRT more common than AVRT)
    - monitor for recurrence
    - treat recurrence with adenosine or longer acting medications
  - rhythm does not convert: atrial flutter, ectopic atrial tachycardia, junctional tachycardia
    - rate control (diltiazem, β-blockers) and consult cardiology
- irregular rhythm
  - probable atrial fibrillation, atrial flutter, or multifocal atrial tachycardia
    - rate control (diltiazem, β-blockers)
**Atrial Fibrillation**
- most common sustained dysrhythmia; no organized P waves (atrial rate >300/min), irregularly irregular heart rate, narrow QRS (typically)
- etiology: HTN, CAD, thyrotoxicosis, EtOH (holiday heart), valvular disease, pericarditis, cardiomyopathy, sick sinus syndrome
- treatment principles: stroke prevention, treat symptoms, identify/treat underlying cause
- decreases cardiac output by 20-30% (due to loss of organized atrial contractions)
- acute management
  - if unstable: immediate synchronized cardioversion
  - if onset of A Fib is >48 h: rate control, anticoagulate 3 wk prior to and 4 wk after cardioversion or do transesophageal echocardiogram to rule out clot
  - if onset <48 h: may cardiovert
    - electrical cardioversion: synchronized direct current (DC) cardioversion
    - chemical cardioversion: procainamide, flecainide, propafenone
- long-term management: rate or rhythm control, consider anticoagulation (CHADS2 score, see Cardiology and Cardiac Surgery, C19)

**Ventricular Tachydysrhythmias (wide QRS)**
- VTach (rate usually 140-200 bpm)
  - definition: 3 or more consecutive ventricular beats at >100 bpm
  - etiology: CAD with MI is most common cause
  - treatment: sustained VTach (>30 s) is an emergency
    - no hemodynamic compromise: synchronized DC cardioversion
    - hemodynamic compromise: synchronized DC cardioversion, lidocaine, amiodarone, procainamide
- ventricular fibrillation: call a code blue, follow ACLS for pulseless arrest
- torsades de points
  - looks like VTach but QRS ‘rotates around baseline’ with changing axis and amplitude (twisted ribbon)
  - etiology: prolonged QT due to drugs (e.g. quinidine, TCAs, erythromycin, quinolones), electrolyte imbalance (hypokalemia, hypomagnesemia), congenital
  - treatment:
    - IV MgSO4, temporary overdrive pacing, isoproterenol
    - correct cause of prolonged QT

**Chronic Obstructive Pulmonary Disease**
- see Respirology, R9
  - progressive development of irreversible airway obstruction, typically caused by smoking
  - acute exacerbation: episode of increased dyspnea, coughing, increase in sputum volume or purulence

**History and Physical Exam**
  - worsening dyspnea or tachypnea
  - acute change in frequency, quantity, and color of sputum production
  - triggers: pneumonia, urinary tract infection, PE, CHF, MI, drugs

**Investigations**
- CBC, electrolytes, ABG, CXR, ECG, PFTs

**Management**
- keep O2 sat 88-92% (be aware when giving O2 to chronic hypercapnic/CO2 retainers but do not withhold O2 if hypoxic)
- apply BiPAP if severe distress, arterial pH <7.35, or hypercapnic
- ipratropium is anticholinergic agent of choice, add salbutamol
- steroids: ipratropium 40 mg PO for 5 d
- antibiotics: TMP-SMX, cephalosporins, respiratory quinolones (if acute change in frequency, quantity, and color of sputum production)
- if life-threatening, ICU admission for ventilation (chance of ventilation dependency)
- lower threshold to admit if comorbid illness

**Disposition**
- can use up to 4-6 puffs qid of ipratropium and salbutamol for exacerbations
- continue antibiotics if started and give tapering steroids
**Congestive Heart Failure**

- **Etiology**
  - decreased myocardial contractility: ischemia, infarction, cardiomyopathy, myocarditis
  - pressure overload states: HTN, valve abnormalities, congenital heart disease
  - restricted cardiac output: myocardial infiltrative disease, cardiac tamponade
  - volume overload

- **Presentation**
  - left-sided heart failure
    - dyspnea, decreased exercise tolerance, paroxysmal nocturnal dyspnea, orthopnea, nocturia, fatigue, possibly altered mental status, syncope, angina, systemic hypotension
  - hypoxia, decreased air entry to lungs, rales, S3 or S4, pulmonary edema on CXR, pleural effusion (usually right sided)
  - right-sided heart failure
    - dependent bilateral pitting edema, JVP elevation, hepatic enlargement, ascites
  - patients often present with a combination of right-sided and left-sided symptoms

- **Investigations**
  - labs: CBC, electrolytes, AST, ALT, bilirubin, Cr, BUN, cardiac enzymes, brain natriuretic peptide
  - CXR (see sidebar, ER32)
  - ECG: look for MI, ischemia (ST elevation/depression, T-wave inversion)
    - in CHF: LVH, atrial enlargement, conduction abnormalities
  - ABG: if severe or refractory to treatment
    - hypoxemia, hypercapnia and acidosis are signs of severe CHF
  - echocardiogram: not usually used in emergency evaluation, previous results may aid in diagnosis
  - may be precipitated by dysrhythmia (e.g. sudden onset AFib) – correct if new
  - rule out serious differentials such as PE, pneumothorax, pneumonia/empyema, COPD exacerbation

- **Management (acute)**
  - ABC, may require intubation if severe hypoxia
  - sit upright, cardiac monitoring and continuous pulse oximetry
  - saline lock IV, Foley catheter (to follow effectiveness of diuresis)
  - 100% O₂ by mask
    - if poor response, may require BiPAP or intubation
  - drugs
    - nitroglycerin 0.3 mg SL q5min prn ± topical nitroglycerine patch (0.2-0.8 mg/h)
      - if not responding or ischemia: 10-200 µg/min IV, titrate
    - diuretic if volume overloaded (e.g. furosemide 40-80 mg IV), use caution if cause is valvulopathy
    - morphine 1-2 mg IV prn
      - if hypotensive: dobutamine (2.5 µg/kg/min IV) or dopamine (5-10 µg/kg/min IV), titrate up to sBP 90-100 mmHg
    - ASA 160 mg chew and swallow
    - treat precipitating factor
    - cardiology or medicine consult

**Deep Vein Thrombosis and Pulmonary Embolism**

- **Risk Factors**
  - Virchow’s triad
    - alterations in blood flow (venous stasis)
    - injury to endothelium
    - hypercoagulable state (including pregnancy, use of OCP, malignancy)
  - clinical risk factors

- **Presentation**
  - DVT: calf pain, leg swelling/erythema/edema, palpable cord on exam; can be asymptomatic
  - PE: dyspnea, pleuritic chest pain, hemoptysis, tachypnea, cyanosis, hypoxia, fever
  - clinical signs/symptoms are unreliable for diagnosis and exclusion of DVT/PE; investigation often needed
  - calculate the PERC (PE rule out criteria) score to assess the need for PE workup before assessing the likelihood of a PE (Wells’ Criteria)
Investigations
- ECG and CXR are useful to look for other causes (e.g., ACS, pneumonia)
- D-dimer is only useful if it is negative in low risk patients (highly sensitive)
- U/S has high sensitivity and specificity for proximal clot but only 73% sensitivity for DVT below the knee (may need to repeat in 1 wk)
- CT angiography has high sensitivity and specificity for PE, may also suggest other etiologies
- V/Q scan useful when CT angiography not available, or patient unable to tolerate IV contrast (e.g., renal failure, allergy)

Management of DVT/PE
- LMWH unless patient also has renal failure
  - dalteparin 200 IU/kg SC q24h or enoxaparin 1.5 mg/kg SC q24h
- warfarin started at same time as LMWH (5 mg PO OD initially)
- LMWH discontinued when INR has been therapeutic (2-3) for 2 consecutive days
  - early ambulation with analgesia is safe if appropriately anticoagulated
- rivaroxaban can be used in both acute management of symptomatic DVT or PE and extended treatment
  - 15 mg PO bid for first 21 days; 20 mg PO daily for remaining treatment (taken with food at approximately the same time each day)
- IVC filter or surgical thrombectomy considered if anticoagulation is contraindicated
- consider thrombolysis if extensive DVT or PE causing hemodynamic compromise
- often can be treated as outpatient, may require analgesia for chest pain (narcotic or NSAID)
- admit if hemodynamically unstable, require supplemental O2, major comorbidities, lack of sufficient social supports, unable to ambulate, need invasive therapy
- consider referral to medicine for coagulopathy and malignancy workup
- long-term anticoagulation
  - if reversible risk factor: 3-6 mo of warfarin
  - idiopathic VTE: may need longer term warfarin (5 yr or more)

**Figure 12. Approach to suspected DVT**

**Figure 13. Approach to suspected PE**
**Diabetic Emergencies**

- see Endocrinology, E11

**Diabetic Ketoacidosis**
- severe insulin deficiency resulting in hyperglycemia (200-1,000 mg/dL), dehydration, and electrolyte abnormalities
- history and physical exam – often young, type 1 DM, may be first presentation of undiagnosed DM (may occur in small percentage of type 2 DM patients)
- early symptoms: polyuria, polydipsia, malaise, nocturia, weight loss
- late signs and symptoms
  - anorexia, N/V, dyspnea (often due to acidosis), fatigue
  - abdominal pain
  - drowsiness, stupor, coma
  - Kussmaul’s respiration
  - fruity acetone breath
- investigations
  - CBC, glucose, electrolytes, BUN/Cr, Ca²⁺, Mg²⁺, PO₄³⁻, urine glucose and ketones
  - ABG
  - ECG (MI possible precipitant; electrolyte disturbances may predispose to dysrhythmia)
- management
  - rehydration
    - bolus of NS, then high rate NS infusion (be aware of overhydration and cerebral edema, especially in pediatric patients)
    - beware of a pseudohyponatremia due to hyperglycemia (add 3 Na⁺ per 18 glucose over 100 mg/dL)
  - potassium
    - essential to avoid hypokalemia: replace KCl (20 mEq/L if adequate renal function and initial K⁺ <5.5 mEq/L)
    - use cardiac monitoring if potassium levels normal or low
  - insulin
    - critical, as this is the only way to turn off gluconeogenesis/ketosis
    - do not give insulin if K⁺ <3.3 mEq/L
    - initial bolus of 5-10 U short-acting/regular insulin (or 0.2 U/kg) IV in adults (controversial – may just start with infusion)
    - followed by continuous infusion at 5-10 U (or 0.1 U/kg) per h
    - add D5W to IV fluids when blood glucose <270 mg/dL to prevent hypoglycemia
  - bicarbonate is not given unless patient is at risk of death or shock (typically pH <7.0)

**Hyperosmolar Hyperglycemic State**
- state of extreme hyperglycemia (800-2,400 mg/dL) due to relative insulin deficiency, increased counter- regulatory hormones, gluconeogenesis, and dehydration (due to osmotic diuresis) in type 2 DM, high mortality (5-20%)
- history and physical exam
  - mental disturbances, coma, delirium, seizures
  - polyuria
  - N/V
- investigations
  - CBC, electrolytes, Cr, BUN, glucose, Mg²⁺, PO₄³⁻, urine glucose and ketones
  - ABG
  - ECG
- management
  - rehydration with IV NS (total water deficit estimated at average 100 cc/kg body weight)
  - O₂ and cardiac monitoring, frequent electrolyte and glucose monitoring
  - insulin as required
  - identify and treat precipitant if present (the 5 Is)
**Hypoglycemia**
- very common ED presentation
- history and physical exam
  - last meal, known DM, prior similar episodes, drug therapy and compliance
  - liver/renal/endocrine/neoplastic disease
  - depression, alcohol or drug use
- management
  - IV access and rapid blood glucose measurement
  - D50W 50 mL IV push, glucose PO if mental status permits
  - O₂, cardiac, frequent blood glucose monitoring
  - thiamine 100 mg IM
  - full meal as soon as mental status permits
  - if episode due to long-acting insulin, or sulfonylureas, watch for prolonged hypoglycemia due to long t₁/₂ (may require admission for monitoring)
  - search for cause (most often due to exogenous insulin, alcohol, or sulfonylureas)

**Electrolyte Disturbances**
- see Nephrology, NP7 and Endocrinology, E38

**Table 16. Electrolyte Disturbances**

<table>
<thead>
<tr>
<th>Electrolyte Disturbance</th>
<th>Common Causes</th>
<th>Symptoms</th>
<th>Treatment</th>
<th>Special Considerations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypernatremia</td>
<td>Inadequate H₂O intake (elderly/disabled) or inappropriate excretion of H₂O (diuretics, Li, and DI)</td>
<td>Lethargy, weakness, irritability, and edema; seizures and coma occur with severe elevations of Na⁺ levels (&gt;158 mEq/L)</td>
<td>Salt restrict and give free water</td>
<td>No more than 12 mEq/L in 24 h drop in Na⁺ (0.5 mEq/L/h) due to risk of cerebral edema, seizures, death</td>
</tr>
<tr>
<td>Hyponatremia</td>
<td>Hypo-osmolar (dilutional e.g. CHF, cirrhosis, ascites) and hyper-osmolar (usually glucose)</td>
<td>Acute: Neurologic symptoms 2º to cerebral edema, headache, decreased LOC, depressed reflexes</td>
<td>Water restrict</td>
<td>Limit total rise to 8 mEq/L in 24 h (0.5 mEq/L/h maximum) as patients are at risk of central pontine myelinolysis</td>
</tr>
<tr>
<td>Hyperkalemia</td>
<td>Rhabdomyolysis, insulin deficiency, metabolic acidosis</td>
<td>Nausea, palpitations, muscle stiffness, areflexia</td>
<td>Protect heart: calcium gluconate Shift K⁺ into cells: insulin, NaHCO₃, salbutamol</td>
<td>ECG: peaked/narrow T wave, decreased P wave, prolonged PR interval, widening of QRS, AV block, ventricular fibrillation</td>
</tr>
<tr>
<td>Hypokalemia</td>
<td>Metabolic alkalosis, insulin, diuretics, anorexia, salbutamol</td>
<td>N/V, fatigue, muscle cramps, constipation</td>
<td>K-Dur™, K⁺ sparing diuretics, IV solutions with 20-40 mEq/L over 3-4 h</td>
<td>ECG: U waves most important, flattened/inverted T waves, prolonged QT, depressed ST May need to restore Mg²⁺</td>
</tr>
<tr>
<td>Hypercalcemia</td>
<td>Hyper-PTH and malignancy account for ~90% of cases</td>
<td>Multisystem including CVS, GI (gastrointestinal), renal (stones), rheumatological, MSK (bones), psychiatric (mood)</td>
<td>Isotonic saline + furosemide if hypervolemic Bisphosphonates, dialysis, chelation (EDTA or oral PO₄³⁻)</td>
<td>Patients with more severe or symptomatic hypercalcemia are usually dehydrated and require saline hydration as initial therapy</td>
</tr>
<tr>
<td>Hypocalcemia</td>
<td>iatrogenic, low Mg²⁺, liver dysfunction, 1º hypo-PTH</td>
<td>Laryngospasm, hyperreflexia, paresthesia, tetany, Chvostek’s and Trousseau’s sign</td>
<td>Acute (ionized Ca²⁺ &lt;2.8 mg/dL) requires immediate treatment: IV calcium gluconate 1-2 g in 10-20 min followed by slow infusion</td>
<td>Prolonged QT interval can arise, leading to dysrhythmia as can upper airway obstruction</td>
</tr>
</tbody>
</table>

**Hypertensive Emergencies**

**Hypertensive Emergency (Hypertensive Crisis)**

**Etiology**
- essential HTN, emotional exertion, pain, use of sympathomimetic drugs (cocaine, amphetamine, etc.), MAOI use with ingestion of tyramine-containing food (cheese, red wine, etc.), pheochromocytoma, pregnancy

**Presentation**
- elevation of systolic and diastolic BP (irrespective of BP) with acute end-organ damage (CNS, renal, CVS, retinal)
Table 17. Signs and Symptoms of Hypertensive Emergencies

</tbody>
</table>

Investigations

- CBC, electrolytes, BUN, Cr, U/A
- peripheral blood smear: to detect microangiopathic hemolytic anemia
- CXR: if SOB or chest pain
- ECG, troponins, CK if chest pain
- CT head: if neurological findings or severe headache
- toxicology screen if sympathomimetic overdose suspected

Management

- in general, the strategy for management is to gradually and progressively reduce BP in 24-48 h
- lower BP by 25% over the initial 60 min by initiating antihypertensive therapy (usually nitroprenus and labetolot) or adjusting antihypertensive
- if preeclampsia, immediately consult OB/GYN (see Obstetrics, OB15)
- if transfer to ICU for further reduction in BP under monitored setting
- in case of ischemic stroke: do not rapidly reduce BP maintain BP >150/100 for 5 d
- in case of aortic dissection: rapid reduction of sBP to 110-120 STAT (do not resuscitate with IV fluids)
- in case of excessive catecholamines: avoid β-blockers (except labetolot)
- in case of ACS: address ischemia initially, then BP

Hypertensive Urgency

- definition: severely elevated BP (usually sBP >180, dBP >115) with no evidence of end-organ damage
- most commonly due to non-adherence with medications
- most commonly due to non-adherence with medications
- treatment: initiate/adjust antihypertensive therapy, monitor in ED (up to 6 h) and discharge with follow up for 48-72 h
- goal: differentiate hypertensive emergencies from hypertensive urgencies

Table 18. Most Commonly Used Agents for the Treatment of Hypertensive Crisis

<td>Phentolamine</td>
<td>5-15 mg q5-15min</td>
<td>1-2 min</td>
<td>3-10 min</td>
<td>Tachycardia, headache, flushing</td>
<td>Catecholamine excess (e.g. pheochromocytoma)</td>
</tr>
</tbody>
</table>

*Hypotension may occur with all of these agents

Stroke

- see Neurology, N47
- can be ischemic (80% of all strokes) or hemorrhagic

Presentation

- sudden onset persisting neurological deficits

Table 19. Signs and Symptoms of Stroke

<table>
<thead>
<tr>
<th>Signs/ Symptoms</th>
<th>General</th>
<th>Language/ Throat</th>
<th>Vision</th>
<th>Coordination</th>
<th>Motor</th>

</tr>
</tbody>
</table>

Investigations

- CBC, electrolytes, blood glucose, coagulation studies ± cardiac biomarkers ± toxicology screen
- non-contrast CT head: look for hemorrhage, ischemia
- ECG ± echocardiogram: rule out atrial fibrillation, acute MI as source of emboli
- other imaging: carotid dopplers, CTA, MRA as appropriate

Exclusion Criteria for tPA:

- Suspected subarachnoid hemorrhage
- Previous intracranial hemorrhage
- Cerebral infarct or severe head injury within the past 3 mo
- Recent pericarditis
- Major surgery within the past 14 d
- Recent LP or arterial puncture at noncompressible site
- Patient is pregnant
- BP >185 mmHg systolic, or >110 mmHg diastolic
- Bleeding diathesis
- Prolonged PTT (more than 40 s) or INR >1.4
- Platelet count <100,000
- Blood glucose <50 or >400 mg/dL
- Intracranial hemorrhage on CT or large volume infarct
- Seizure at onset causing deficit
- Previously ADL dependent (clinical judgment)

</tbody>
</table>
Management

- Thrombolysis: immediate assessment for eligibility; need acute onset, <4.5 h from drug administration time AND compatible physical findings AND normal CT with no bleed
- Intubation with RSI if GCS ≤8, rapidly decreasing GCS, or inadequate airway protection reflexes
- Elevating head of bed if risk of elevated ICP, aspiration, or worsening cardiopulmonary status
- NPO, IV ± cardiac monitoring
  - Judge fluid rate carefully to avoid overhydration (cerebral edema) as well as underhydration (underperfusion of the ischemic penumbra)
  - BP control: only treat severe HTN (sBP >200, dBP >120, mean arterial BP >140) or HTN associated with hemorrhagic stroke transformation, cardiac ischemia, aortic dissection, or renal damage; use IV nitroprusside or labetalol
  - Glycemic control: keep fasting glucose <117 mg/dL in acute phase (5 d)
- Cerebral edema control: hyperventilation, mannitol to decrease ICP if necessary
- Consult neurosurgery, neurology, medicine as indicated

Medications

- Acute ischemic stroke: thrombolytics (rt-PA, e.g. alteplase) if within 4.5 h of symptom onset with no evidence of hemorrhage on CT scan
- Antiplatelet agents: prevent recurrent stroke or stroke after TIAs, e.g. Aspirin® (1st line); clopidogrel, Aggrenox® (2nd line)
- Anticoagulation: DVT prophylaxis if immobile; treat atrial fibrillation if present

Gynecologic/Urologic Emergencies

Vaginal Bleeding

- See Gynecology, GY6 and Obstetrics, OB21

Etiology

- Pregnant patient
  - 1st/2nd trimester pregnancy: ectopic pregnancy, abortion (threatened, incomplete, complete, missed, inevitable, septic), molar pregnancy, implantation bleeding, friable cervix (most common cause)
  - 2nd/3rd trimester pregnancy: placenta previa, placental abruption, premature rupture of membranes, preterm labor
  - Other: trauma, bleeding cervical polyp, passing of mucous plug
- Postpartum
- Postpartum hemorrhage, uterine inversion, retained placental tissue, endometritis
- Non-pregnant patients
  - Dysfunctional uterine bleeding, uterine fibroids, pelvic tumors, trauma, endometriosis, PID, exogenous hormones

History

- Characterize bleeding (frequency, duration, number of pads/tampons, cyclicity)
- Pain, if present (OPQRSTU)
- Menstrual history, sexual history, STD history, syncope/pre-syncope
- Details of pregnancy, including gush of fluid and fetal movement (>20 wk)

Physical Exam

- ABC (especially noting postural BP/HR and mucous membrane)
- Abdominal examination (peritoneal signs, tenderness, distention, mass)
- Speculum examination (NOT IF 2nd/3rd trimester bleeding; perform only when placenta previa is ruled out with U/S)
  - Look for active bleeding, trauma/anomaly, and cervical dilatation
  - Use sterile speculum if pregnant
- Bimanual examination (cervical tenderness, size of uterus, cervical length/dilatation)
  - Sterile gloves if pregnant

Investigations

- β-hCG test for all patients with childbearing potential
- CBC, blood and Rh type, quantitative β-hCG, PTT, INR
- Type and cross if significant blood loss
- Transvaginal U/S (rule out ectopic pregnancy and spontaneous abortion)
- Abdominal U/S (rule out placenta previa and fetal demise)
- Postpartum
  - U/S for retained products
  - β-hCG if concerned about retained tissue

7 Causes of Emboli from the Heart

- Atrial fibrillation
- MI
- Endocarditis
- Valvular disease
- Dilated cardiomyopathy
- Left heart myxoma
- Prosthetic valves

Vaginal bleeding can be life-threatening. Always start with ABCs and ensure your patient is stable.
Vaginal bleeding (and its underlying causes) can be a very distressing event for patients; ensure appropriate support is provided.

Need β-hCG ≥1,200 to see intrauterine changes on transvaginal U/S
An ectopic pregnancy can be ruled out by confirming an intrauterine pregnancy by bedside U/S unless the patient is using IVF.
Management

- **ABCs**
- pulse oximeter and cardiac monitors if unstable
- Rh immune globulin (Rhogam®) for vaginal bleeding in pregnancy and Rh-negative mother
- 1st/2nd trimester pregnancy
  - ectopic pregnancy: definitive treatment with surgery or methotrexate
  - intrauterine pregnancy, no concerns of coexistent ectopic: discharge patient with obstetrics follow-up
  - U/S indeterminate or β-hCG >1,000-2,000 IU: further workup and/or gynecology consult
  - abortions: if complete, discharge if stable; for all others, acquire gynecology consult
- 2nd/3rd trimester pregnancy
  - placenta previa or placental abruption: obstetrics consult for possible admission
- postpartum
  - manage ABCs: start 2 large bore IV rapid infusion, type and cross 4 units of blood, consult OB/GYN immediately
- non-pregnant
  - dysfunctional uterine bleeding (prolonged or heavy flow ± breakthrough bleeding and without ovulation, a diagnosis of exclusion)
    - <35-40 yr of age: Provera® 10 mg PO OD x 10 d, warn patient of a withdrawal bleed, discharge if stable
    - if unstable, admit for IV hormonal therapy, possible D&C
    - >35-40 yr of age: uterine sampling necessary prior to initiation of hormonal treatment to rule out endometrial cancer, U/S for any masses felt on exam
    - tranexamic acid (Cyklokapron®) to stabilize clots
  - structural abnormalities: fibroids or uterine tumors may require excision for diagnosis/treatment, U/S for workup of other pelvic masses, Pap smear/biopsy for cervical lesions

Disposition

- the decision to admit or discharge should be based on the stability of the patient, as well as the nature of the underlying cause; consult gynecology for admitted patients
- if patient can be safely discharged, ensure follow up with family physician or gynecologist
  - instruct patient to return to ED for increased bleeding, presyncope

Pregnant Patient in the ED

Nephrolithiasis (Renal Colic)

- see Urology, U16

Epidemiology and Risk Factors

- 10% of population (twice as common in males)
- recurrence 50% at 5 yr
- peak incidence 30-50 yr of age
- 75% of stones <5 mm pass spontaneously within 2 wk, larger stones may require consultation

Clinical Features

- urinary obstruction → upstream distention of ureter or collecting system → severe colicky pain
- may complain of pain at flank, groin, testes, or tip of penis
- writhing, never comfortable, N/V, hematuria (90% microscopic), diaphoresis, tachycardia, tachypnea
- occasionally symptoms of trigonal irritation (frequency, urgency)
- fever, chills, rigors in secondary pyelonephritis
- peritoneal findings/anterior abdominal tenderness usually absent

Kidney Stones

- 80% Calcium oxalate
- 10% Struvite
- 10% Uric acid

Classifying Miscarriage (Abortion)

- Missed: non-viable intrauterine pregnancy
- Threatened: viable intrauterine pregnancy with os closed
- Inevitable: os opened, no products of conception passed
- Incomplete: products of conception partially expelled
- Complete: products of conception completely expelled
- Septic: any of above with presence of infection (usually incomplete)
- Recurrent: >3 spontaneous abortions (recurrent pregnancy loss)
Differential Diagnosis of Renal Colic

- acute ureteric obstruction
- acute abdomen: biliary, bowel, pancreas, AAA
- gynecological: ectopic pregnancy, torsion/rupture of ovarian cyst
- pyelonephritis (fever, chills, pyuria, vomiting)
- radiculitis (L1): herpes zoster, nerve root compression

Investigations

- screening
  - CBC → elevated WBC in presence of fever suggests infection
  - electrolytes, Cr, BUN → to assess renal function
  - U/A: R&M (WBCs, RBCs, crystals), C&S
- imaging
  - non-contrast spiral CT is the study of choice
  - abdominal U/S may demonstrate stone or hydronephrosis (consider in females of childbearing age)
  - AXR will identify large radioopaque stones (calcium, struvite, and cystine stones), but may miss smaller stones, uric acid stones, or stones overlying bony structures; consider as an initial investigation in patients who have a history of radioopaque stones and similar episodes of acute flank pain (CT necessary if film is negative)
- strain all urine → stone analysis

Management

- analgesics: NSAIDs (usually ketorolac [Toradol®], preferable over opioids), antiemetics, IV fluids
- urology consult may be indicated, especially if stone >5 mm, or if patient has signs of obstruction or infection
- α-blocker (e.g. tamsulosin) helpful to increase stone passage in select cases

Disposition

- most patients can be discharged
- ensure patient is stable, has adequate analgesia, and is able to tolerate oral medications
- may advise hydration and limitation of protein, sodium, oxalate, and alcohol intake

Ophthalmologic Emergencies

- see Ophthalmology, OP5, OP42

History and Physical Exam

- patient may complain of pain, tearing, itching, redness, photophobia, foreign body sensation, trauma
- mechanism of foreign body insertion – if high velocity injury suspected (welding, metal grinding, metal striking metal), must obtain orbital x-rays, U/S, or CT scan to exclude presence of intraocular metallic foreign body
- visual acuity in both eyes, pupils, extraocular structures, fundoscopy, tonometry, slit lamp exam

Management of Ophthalmologic Foreign Body

- copious irrigation with saline for any foreign body
- remove foreign body under slit lamp exam with cotton swab or sterile needle
- antibiotic drops qid until healed
- patching may not improve healing or comfort – do not patch contact lens wearers
- limit use of topical anesthetic to examination only
- consider tetanus prophylaxis
- ophthalmology consult if globe penetration suspected

Indications for Admission to Hospital

- Intractable pain
- Fever (suggests infection) or other evidence of pyelonephritis
- Single kidney with ureteral obstruction
- Bilateral obstructing stones
- Intractable vomiting
- Compromised renal function

Other Ophthalmologic Emergencies

- Infectious: Red eye, endophthalmitis, hypopyon
- Trauma: Globe rupture, orbital blow-out fractures, corneal injuries, eyelid laceration, hyphema, lens dislocation, retrobulbar hemorrhage
- Painful vision loss: Acute iritis, corneal abrasion, globe rupture, lens dislocation, retrobulbar hemorrhage, optic neuritis, temporal arteritis, endophthalmitis, keratitis
- Painless vision loss: Central retinal vein occlusion, amaurosis fugax, occipital stroke

Contraindications to Pupil Dilation

- Shallow anterior chamber
- Iris-supported lens implant
- Potential neurological abnormality requiring pupillary evaluation
- Caution with CV disease – mydriatics can cause tachycardia

### Dermatologic Emergencies

#### Life-Threatening Dermatoses

**Rash Characteristics**

**A. Diffuse Rashes**

- **SSSS**
  - caused by an exotoxin from infecting strain of coagulase-positive *S. aureus*
  - mostly occurs in children
  - prodrome: fever, irritability, malaise, and skin tenderness
  - sudden onset of diffuse erythema: skin is red, warm, and very tender
  - flaccid bullae that are difficult to see, then desquamate in large sheets
  - Nikolsky’s sign: gentle lateral stroking of skin causes epidermis to separate

- **TEN (≥30% of BSA)**
  - see Dermatology, D21
  - caused by drugs (e.g. phenytoin, sulfas, penicillins, and NSAIDs), bone marrow transplantation, and blood product transfusions
  - usually occurs in adults
  - diffuse erythema followed by necrosis
  - severe mucous membrane blistering
  - entire epidermis desquamation
  - high mortality (>50%)

- **TSS**
  - see Infectious Diseases, ID24
  - caused by superantigen from *S. aureus* or GAS activating T-cell and cytokines
  - patient often presents with onset of shock and multi-organ failure, fever
  - diffuse erythematous macular rash
  - at least 3 organ systems involved: CNS, respiratory, GI, muscular, mucous membranes, renal, liver, hematologic, and skin (necrotizing fasciitis, gangrene)

- **vesicobullous lesions**
  - EM
  - see Dermatology, D21
  - immunologic reaction to herpes simplex
  - viral prodrome 1-14 d before rash
  - “target lesion”: central gray bulla or wheal surrounded by concentric rings of erythema and normal skin
SJS (<10% of BSA)
- see Dermatology, D21
- related to drugs such as antiepileptics and biologic agents (e.g. infliximab)
- EM with constitutional symptoms and mucous membrane involvement (milder mucous membrane involvement than TEN)

B. Discrete Lesions
- pyoderma gangrenosum
  - often associated with immunocompromised patients (HIV, leukemia, or lymphoma) with Gram-negative sepsis
  - often occurs in arms, hands, feet, or perineal region
  - usually begins as painless macule-vesicle → pustule/bulla on red/blue base → sloughing, leaving a gangrenous ulcer
- DGI
  - see Dermatology, D31
  - fever, skin lesions (pustules/vesicles on erythematous base ~5 mm in diameter), arthritis (joint swelling and tenderness), and septic arthritis (in larger joints, such as knees, ankles, and elbows)
  - most commonly in gonococcus positive women during menstruation or pregnancy
  - skin lesions usually appear in extremities and resolve quickly (<7 d)
- meningococcemia
  - flu-like symptoms of headache, myalgia, N/V
  - petechial, macular, or maculopapular lesions with gray vesicular centers
  - usually a few millimeters in size, but may become confluent and hemorrhagic
  - usually appear in extremities, but may appear anywhere
  - look for signs of meningeal irritation: Brudzinski, Kernig, nuchal rigidity, jolt accentuation

History and Physical Exam
- determine onset, course, and location of skin lesions
- fever, joint pain
- associated symptoms: CNS, respiratory, GU, GI, renal, liver, mucous membranes
- medication history
- vitals

Investigations
- immediate consultation if patient unstable
- CBC, electrolytes, Cr, AST, ALT, ALP, blood culture, skin biopsy, serum immunoglobulin levels (serum IgE)

Management
- general: judicious IV fluids and electrolyte control, consider vasopressors if hypotensive, prevention of infection
- determine if admission and consult needed: dermatology or infectious diseases
- specific management is determined by etiology
  - SSSS, TSS, DGI, and meningococcemia
    - IV antibiotics
  - EM, SJS, and TEN
    - stop precipitating medication
    - fluids
    - symptomatic treatment: antihistamines, antacids, topical corticosteroids, systemic corticosteroids (controversial), prophylactic oral acyclovir, consider IVIg
    - TEN: debride necrotic tissue

Disposition
- most cases will require urgent care and hospitalization
- TEN: early transfer to burn center improves outcome

Environmental Injuries

Heat Exhaustion and Heat Stroke
- predisposing factors: young persons who overexert themselves, older adults who cannot dissipate heat at rest (e.g. using anticholinergic drugs such as antihistamines or TCAs), and patients with schizophrenia who are using anticholinergic or antiepileptic medications

Heat Exhaustion
- clinical features relate to loss of circulating volume caused by exposure to heat stress
- "water depletion": heat exhaustion occurs if lost fluid not adequately replaced
- "salt depletion": heat exhaustion occurs when losses replaced with hypotonic fluid
Heat Stroke
- life-threatening emergency resulting from failure of normal compensatory heat-shedding mechanisms
- divided into classical and exertional subtypes
- if patient does not respond relatively quickly to cooling treatments, consider other possible etiologies of hyperpyrexia (e.g. meningitis, thyroid storm, anticholinergic poisoning, delirium tremens, other infections)

Table 24. Heat Exhaustion vs. Heat Stroke

<table>
<thead>
<tr>
<th>Clinical Features</th>

<td>Avoid α-agonists (e.g. epinephrine), peripheral vasoconstriction, and antipyretics (e.g. ASA)</td>
<td>Avoid α-agonists (e.g. epinephrine), peripheral vasoconstriction, and antipyretics (e.g. ASA)</td>
</tr>
</tbody>
</table>

Hypothermia and Cold Injuries

HYPOTHERMIA
- predisposing factors: extremes of age, lack of housing, drug overdose, EtOH ingestion, trauma (incapacitating), cold water immersion, outdoor sports
- treatment based on re-warming and supporting cardiorespiratory function
- complications: coagulopathy, acidosis, ventricular dysrhythmias (VFib), asystole, volume and electrolyte depletion
- labs: CBC, electrolytes, ABG, serum glucose, Cr/BUN, Mg²⁺, Ca²⁺, amylase, coagulation profile
- imaging: CXR (aspiration pneumonia, pulmonary edema are common)
- monitors: ECG, rectal thermometer, Foley catheter, NG tube, monitor metabolic status frequently

Table 25. Classification of Hypothermia

<thead>
<tr>
<th>Class</th>
<th>Temp</th>
<th>Symptoms/Signs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mild</td>
<td>89.6 - 94.8°F</td>
<td>Tachypnea, tachycardia, ataxia, dysarthria, shivering</td>
</tr>
<tr>
<td>Moderate</td>
<td>82.4 - 88.4°F</td>
<td>Loss of shivering, dysrhythmias, Osborne (J) waves on ECG, decreased LOC, combative behavior, muscle rigidity, dilated pupils</td>
</tr>
<tr>
<td>Severe</td>
<td>&lt;82.4°F</td>
<td>Coma, hypotension, acidemia, VFib, asystole, flaccidity, apnea</td>
</tr>
</tbody>
</table>

Re-warming Options
- gentle fluid and electrolyte replacement in all (due to cold diuresis)
- Passive External Re-warming
  - suitable for most stable patients with core temperature >90°F
  - involves covering patient with insulating blanket; body generates heat and re-warms through metabolic process, shivering
- Active External Re-warming
  - involves use of warming blankets
  - beware of "afterdrop" phenomenon
  - safer when done in conjunction with active core re-warming
- Active Core Re-warming
  - generally for patients with core temperature <90°F, and/or with cardiovascular instability
  - avoids "afterdrop" seen with AER alone
  - re-warm core by using
    - warmed humidified oxygen, IV fluids
    - peritoneal dialysis with warm fluids
    - gastric/colonic/pleural irrigation with warm fluids
    - external circulation (cardiopulmonary bypass machine) is most effective and fastest

Afterdrop Phenomenon
Warming of extremities causes vasodilation and movement of cool pooled blood from extremities to core, resulting in a drop in core temperature leading to cardiac arrest
Approach to Cardiac Arrest in the Hypothermic Patient

- do all procedures gently or may precipitate VFib
- check pulse and rhythm for at least 1 min; may have profound bradycardia
- if any pulse at all (even very slow) do NOT do CPR
  - if in VFib try to defibrillate up to maximum 3 shocks if core temperature <86°F
  - intubate if required, ventilate with warmed, humidified O₂
- medications (vasopressors, antidysrhythmics) may not be effective at low temperatures
  - controversial; may try one dose
- focus of treatment is re-warming

FROSTBITE

Classification

- ice crystals form between cells
- classified according to depth – similar to burns (1st to 3rd degree)
  - 1st degree
    - symptoms: initial paresthesia, pruritus
    - signs: erythema, edema, hyperemia, no blisters
  - 2nd degree
    - symptoms: numbness
    - signs: blistering (clear), erythema, edema
  - 3rd degree
    - symptoms: pain, burning, throbbing (on thawing); may be painless if severe
    - signs: hemorrhagic blisters, skin necrosis, edema, no movement

Management

- treat for hypothermia: O₂, IV fluids, maintenance of body warmth
- remove wet and constrictive clothing
- immerse in 104-107.6°F agitated water for 10-30 min (very painful; administer adequate analgesia)
- clean injured area and leave it open to air
- consider aspiration/debridement of blisters (controversial)
- debride skin
- tetanus prophylaxis
- consider penicillin G as frost bite injury at high risk of infection
- surgical intervention may be required to release restrictive eschars
- never allow a thawed area to re-chill/freeze

Burns

- see Plastic Surgery, PL16

Physical Exam

- burn size
  - rule of nines; does not include 1st degree burns
- burn depth
  - superficial: epidermis only (e.g. sunburn)
  - partial thickness: into superficial dermis or hair follicles, sweat glands
  - full thickness: all layers of the skin
  - deep: involvement of fat, muscle, even bone

Management

- remove noxious agent/stop burning process
- establish airway if needed (indicated with burns >40% BSA or smoke inhalation injury)
- resuscitation for 2nd and 3rd degree burns (after initiation of 2 large bore IVs)
- fluid boluses if unstable
  - Parkland Formula: Ringer’s lactate 4 cc/kg/% BSA burned; give half in first 8 h, half in next 16 h; maintenance fluids are also required if patient cannot tolerate PO hydration
- urine output is best measure of resuscitation, should be 40-50 cc/h or 0.5 cc/kg/h; avoid diuretics
- pain relief: continuous morphine infusion with breakthrough bolus
- investigations: CBC, electrolytes, U/A, CXR, ECG, ABG, carboxyhemoglobin
- burn wound care: prevent infection, clean/debride with mild soap and water, sterile dressings
- escharotomy or fasciotomy for circumferential burns (chest, extremities)
- topical antibiotics, systemic antibiotics infrequently indicated
- tetanus prophylaxis if burn is deeper than superficial dermis

Disposition

- admit
  - 2nd degree burns >10% BSA or any significant 3rd degree burns
  - 2nd degree burns on face, hands, feet, perineum, or across major joints
  - electrical, chemical burns, and inhalation injury
  - burn victims with underlying medical problems or immunosuppressed patients
Inhalation Injury

Etiology
- CO or cyanide poisoning
- direct thermal injury: limited to upper airway
- smoke causes bronchospasm and edema from particulate matter and toxic inhalants (tissue asphyxiates, pulmonary irritants, systemic toxins)

History and Physical Exam
- risk factors: closed space fires, period of unconsciousness, noxious chemicals involved
- cherry red skin (unreliable, usually post-mortem finding)
- singed nasal hairs, soot on oral/nasal membranes, sooty sputum
- hoarseness, stridor, dyspnea
- decreased LOC, confusion
- PO2 normal but O2 saturation low suggests CO poisoning

Investigations
- measure carboxyhemoglobin levels, co-oximetry
- ABG
- CXR ± bronchoscopy

Management
- CO poisoning: 100% O2 ± hyperbaric O2 (controversial)
- direct thermal injury: humidified oxygen, early intubation, pulmonary toilet, bronchodilators

Bites

MAMMALIAN BITES
- see Plastic Surgery, PL10

History
- time and circumstances of bite, symptoms, allergies, tetanus immunization status, comorbid conditions, rabies risks, HIV/hepatitis risk (human bite)
- high morbidity associated with clenched fist injuries, “fight bites”

Physical Exam
- assess type of wound: abrasion, laceration, puncture, crush injury
- assess for direct tissue damage: skin, bone, tendon, neurovascular status

Investigations
- if bony injury or infection suspected, check for fracture and gas in tissue with x-rays
- get skull films in children with scalp bite wounds ± CT to rule out cranial perforation

Initial Management
- wound cleansing and copious irrigation as soon as possible
- irrigate/debride puncture wounds if feasible, but not if sealed or very small openings; avoid hydrodissection along tissue planes
- debridement is important in crush injuries to reduce infection and optimize cosmetic and functional repair
- culture wound if signs of infection (erythema, necrosis, or pus); obtain anaerobic cultures if wound foul smelling, necrotizing, or abscess; notify lab that sample is from bite wound

Prophylactic Antibiotics
- types of infections resulting from bites: cellulitis, lymphangitis, abscesses, tenosynovitis, osteomyelitis, septic arthritis, sepsis, endocarditis, meningitis
- a 3-5 d course of antibiotics is recommended for all bite wounds to the hand and should be considered in other bites if any high-risk factors present (efficacy not proven)
- dog and cat bites (pathogens: Pasteurella multocida, S. aureus, S. viridans)
  - 80% of cat bites, 5% of dog bites become infected
  - 1st line: amoxicillin + clavulanic acid
- human bites (pathogens: Eikenella corrodens, S. aureus, S. viridans, oral anaerobes)
  - 1st line: amoxicillin + clavulanic acid
- rabies (see Infectious Diseases, ID21)
  - reservoirs: warm-blooded animals except rodents, lagomorphs (e.g. rabbits)
  - post-exposure vaccine is effective; treatment depends on local prevalence
- suturing
  - vascular structures (i.e. face and scalp) are less likely to become infected, therefore consider suturing
  - allow avascular structures (i.e. pretibial regions, hands, and feet) to heal by secondary intention
- tetanus immunization if >10 yr or incomplete primary series

Consider Admission if:
- Moderate to severe infections
- Infections in immunocompromised patients
- Not responding to oral therapy
- Penetrating injuries to tendons, joints, CNS
- Open fractures
SNAKE BITES
- history, physical exam, investigations, and initial management similar to mammalian bites
- additional management issues
  - snake bites are rarely fatal, but proper precautions must be taken
  - supportive management, observe for compartment syndrome, analgesia, tetanus prophylaxis
  - contact State Poison Information Center for consultation
  - for the Massasauga rattlesnake ONLY: if no signs of local tissue damage AND an INR is normal at 6 h after the bite, the patient may be discharged
  - there is NO evidence that constriction bands are helpful AND can be harmful
- if envenomation present, administer antivenom as directed by local Poison Information Center

INSECT BITES
- bee stings
  - 5 types of reactions to stings (local, large local, systemic, toxic, unusual)
  - history and physical exam key to diagnosis; no lab test will confirm
  - investigations: CBC, electrolytes, BUN, Cr, glucose, ABGs, ECG
  - ABC management, epinephrine 0.1 mg IV over 5 min if shock, antihistamines, cimetidine 300 mg IV/IM/PO, steroids, β-agonists for SOB/wheezing 3 mg in 5 mL NS via nebulizer, local site management
- West Nile virus (see Infectious Diseases, ID25)

Near Drowning
- most common in children <4 yr and teenagers
- causes lung damage, hypoxemia, and may lead to hypoxic encephalopathy
- must also assess for shock, C-spine injuries, hypothermia, and scuba-related injuries (barotrauma, air emboli, lung re-expansion injury)
- complications: volume shifts, electrolyte abnormalities, hemolysis, rhabdomyolysis, renal, DIC

Physical Exam
- ABCs, vitals: watch closely for hypotension
- lungs: rales (ARDS, pulmonary edema), decreased breath sounds (pneumothorax)
- CVS: murmurs, dysrhythmias, JVP (CHF, pneumothorax)
- H&N: assess for C-spine injuries
- neuro: GCS or AVPU, pupils, focal deficits

Investigations
- labs: CBC, electrolytes, ABGs, Cr, BUN, INR, PTT, U/A (drug screen, myoglobin)
- imaging: CXR (pulmonary edema, pneumothorax) ± C-spine imaging
- ECG

Management
- ABCs, treat for trauma, shock, hypothermia
- cardiac and O2 monitors, IV access
- intensive respiratory care
  - ventilator assistance if decreased respirations, pCO₂ >50 mmHg, or pO₂ <60 mmHg on maximum O₂
  - may require intubation for airway protection, ventilation, pulmonary toilet
  - high flow O₂/CPAP/BiPAP may be adequate but some may need mechanical ventilation with positive end-expiratory pressure
- dysrhythmias: usually respond to corrections of hypoxemia, hypothermia, and acidosis
- vomiting: very common, NG suction to avoid aspiration
- convulsions: usually respond to O₂; if not, diazepam 5-10 mg IV slowly
- bronchospasm: bronchodilators
- bacterial pneumonia: not necessary to prophylax with antibiotics unless contaminated water or hot-tub (Pseudomonas)
- always initiate CPR in drowning-induced cardiac arrest even if patient hypothermic; continue CPR until patient is fully rewarmed

Disposition
- non-significant submersion: discharge after short observation
- significant submersion (even if asymptomatic): long period of observation (24 h) as pulmonary edema may appear late
- CNS symptoms or hypoxemia: admit
- severe hypoxemia, decreased LOC: ICU
Toxicology

“ABCD3EFG“ of Toxicology

- basic axiom of care is symptomatic and supportive treatment
- address underlying problem only once patient is stable
  
  A  Airway (consider stabilizing the C-spine)
  B  Breathing
  C  Circulation
  D1  Drugs
    * ACLS as necessary to resuscitate the patient
    * universal antidotes
  D2  Draw bloods
  D3  Decontamination (decrease absorption)
  E  Expose (look for specific toxidromes)/Examine the patient
  F  Full vitals, ECG monitor, Foley, X-rays
  G  Give specific antidotes and treatments

- go back and reassess
- call Poison Information Center
- obtain corroborative history from family, bystanders

D1 – Universal Antidotes

- treatments that will not harm patients and may be essential

Dextrose (glucose)
- give to any patient presenting with altered LOC
- measure blood glucose prior to glucose administration if possible
- adults: 0.5-1.0 g/kg (1-2 mL/kg) IV of D50W
- children: 0.25 g/kg (2-4 mL/kg) IV of D25W

Oxygen
- do not deprive a hypoxic patient of oxygen no matter what the antecedent medical history (i.e. even COPD with CO2 retention)
- if depression of hypoxic drive, intubate and ventilate
- exception: paraquat or diquat (herbicides) inhalation or ingestion (oxygen radicals increase morbidity)

Naloxone (central µ-receptor competitive antagonist, shorter t1/2 than naltrexone)
- antidote for opioids: administration is both diagnostic and therapeutic (1 min onset of action)
- used for the undifferentiated comatose patient
- loading dose
  - adults
    * response to naloxone can be drastic, so stepwise delivery of initial 2 mg bolus is recommended
    * draw up 2 mg to deliver IV/IM/SL/SC or via ETT (ETT dose = 2-2.5x IV dose)
      - 1st dose 0.4 mg
      - if no response, deliver 2nd dose 0.6 mg
      - if still no response, deliver remaining 1 mg
  - child
    * 0.01 mg/kg initial bolus IV/IO/ETT
    * 0.1 mg/kg if no response and opioid still suspected to max of 10 mg
- maintenance dose
  - may be required because half-life of naloxone (30-80 min) is much shorter than many opioids
  - hourly infusion rate at 2/3 of initial dose that produced patient arousal

Thiamine (Vitamin B1)
- 100 mg IV/IM with IV/PO glucose to all patients
- given to prevent/treat Wernicke's encephalopathy
- a necessary cofactor for glucose metabolism (may worsen Wernicke's encephalopathy if glucose given before thiamine), but do not delay glucose if thiamine unavailable
- must assume all undifferentiated comatose patients are at risk
D2 – Draw Bloods

- essential tests
  - CBC, electrolytes, BUN/Cr, glucose, INR/PTT, osmolality
  - ABGs, measure O₂ sat
  - ASA, acetaminophen, EtOH levels
- potentially useful tests
  - drug levels – this is NOT a serum drug screen
  - Ca²⁺, Mg²⁺, PO₄³⁻
  - protein, albumin, lactate, ketones, liver enzymes, CK – depending on drug and clinical presentation

Serum Drug Levels
- treat the patient, not the drug level
- negative toxicology screen does not rule out a toxic ingestion – signifies only that the specific drugs tested were not detectable in the specimen
- specific drugs available on general screen vary by institution; check before ordering
- urine screens also available (qualitative only)

Table 26. Toxic Gaps (see Nephrology, NP14)

D3 – Decontamination and Enhanced Elimination

Ocular Decontamination
- saline irrigation to neutralize pH; alkali exposure requires ophthalmology consult

Dermal Decontamination (wear protective gear)
- remove clothing, brush off toxic agents, irrigate all external surfaces

Gastrointestinal Decontamination
- single dose activated charcoal
  - adsorption of drug/toxin to AC prevents availability
  - contraindications: caustics, small bowel obstruction, perforation
  - dose: 10 g/g drug ingested or 1g/kg body weight
  - odorless, tasteless, prepared as slurry with H2O
- whole bowel irrigation
  - 500 mL/h (child) to 2,000 mL/h (adult) of polyethylene glycol solution by mouth until clear effluent per rectum
  - start slow (500 mL in an adult) and aim to increase rate hourly as tolerated
  - indications
    - awake, alert, can be nursed upright OR intubated and airway protected
    - delayed release product
    - drug/toxin not bound to charcoal
    - drug packages (if any evidence of breakage → emergency surgery)
  - contraindications
    - evidence of ileus, perforation, or obstruction
  - surgical removal in extreme cases
    - indicated for drugs that are toxic, form concretions, or cannot be removed by conventional means
- no evidence for the routine use of cathartics (i.e. ipecac)

Urine Alkalization
- may be used for: ASA, methotrexate, phenobarbital, chlorpropamide
- weakly acidic substances can be trapped in alkali urine (pH >7.5) to increase elimination

Multidose Activated Charcoal
- may be used for: carbamazepine, phenobarbital, quinine, theophylline
- for toxins which undergo enterohepatic recirculation
- removes drug that has already been absorbed by drawing it back into GI tract
- various regimens: 12.5 g (1/4 bottle) PO q1h or 25 g (1/2 bottle) PO q2h until non-toxic

Hemodialysis
- indications/criteria for hemodialysis
  - toxins that have high water solubility, low protein binding, low molecular weight, adequate concentration gradient, small volume of distribution, or rapid plasma equilibration
  - removal of toxin will cause clinical improvement
  - advantage is shown over other modes of therapy
  - predicted that drug or metabolite will have toxic effects
  - impairment of normal routes of elimination (cardiac, renal, or hepatic)
  - clinical deterioration despite maximal medical support
- useful for the following toxins
  - methanol
  - lithium
  - ethylene glycol
  - phenobarbital
  - salicylates
  - chloral hydrate (→ trichloroethanol)
  - others include theophylline, carbamazepine, valproate, methotrexate

E – Expose and Examine the Patient
- vital signs (including temperature), skin (needle tracks, color), mucous membranes, pupils, odors, and CNS
- head-to-toe survey including
  - C-spine
  - signs of trauma, seizures (incontinence, “tongue biting”, etc.), infection (meningismus), or chronic alcohol/drug abuse (track marks, nasal septum erosion)
- mental status

Position Paper Update: Ipecac Syrup for Gastrointestinal Decontamination
Clin Toxicol 2013;51:134-139
Study: Systematic review of 12 new studies (2003-2011) and summary of older studies (animal studies, volunteer studies, case reports).
Conclusions: There is debate in the literature as to whether or not the use of ipecac should be completely abandoned, or whether it may remain useful in certain special circumstances. Concerns regarding the use of ipecac include the variability of its effects depending on elapsed time of administration and its interference with other treatments such as activated charcoal. Furthermore, ipecac use has a number of side effects, such as diarrhea, drowsiness, and prolonged vomiting, as well as some rare side effects which may contribute to death. Despite these, ipecac has a high margin of safety. While routine administration of ipecac is not appropriate, it may be beneficial in certain circumstances. For example, its use may be considered when there is a substantial risk of serious toxicity, there are no contraindications (such as high risk of aspiration), no alternative treatment option exists (or when the administration of ipecac will have no effect on the alternative treatment option), and there can be timely delivery of ipecac (<90 min).

<tr>
<td>Calcium Channel Blockers</td>
<td>Decontaminate (activated charcoal) CaCl₂ 1-4 g of 10% solution IV if hypotensive Other: high dose insulin euglycemia, inotropes or intralipids</td>
<td>Order ECG, electrolytes (especially Ca²⁺, Mg²⁺, Na⁺, K⁺)</td>
</tr>
<tr>
<td>Cocaine</td>
<td>Decontaminate (activated charcoal) if oral Aggressive supportive care</td>
<td>β-blockers are contraindicated in acute cocaine toxicity Intralipid for life-threatening symptoms</td>
</tr>
<tr>
<td>CO Poisoning</td>
<td>See Inhalation Injury, ER46 Supportive care 100% O₂</td>
<td></td>
</tr>
<tr>
<td>Cyanide</td>
<td>Hydroxocobalamin</td>
<td>Use for life-threatening dysrhythmias unresponsive to conventional therapy, 6 h serum digoxin &gt;9.4 mg/mL, initial K⁺ &gt;5 mEq/L, ingestion &gt;10 mg (adult)/&gt;4 mg (child) Common dysrhythmias includeVFib, VTach, and conduction blocks</td>
</tr>
<tr>
<td>Digoxin</td>
<td>Decontaminate (activated charcoal) Digoxin-specific Ab fragments 10-20 vials IV if acute; 3-4 if chronic 1 vial (40 mg) neutralizes 0.5 mg of toxin</td>
<td>Use for life-threatening dysrhythmias unresponsive to conventional therapy, 6 h serum digoxin &gt;9.4 mg/mL, initial K⁺ &gt;5 mEq/L, ingestion &gt;10 mg (adult)/&gt;4 mg (child) Common dysrhythmias includeVFib, VTach, and conduction blocks</td>
</tr>
<tr>
<td>Ethanol</td>
<td>Thiamine 100 mg IM/IV Manage airway and circulatory support</td>
<td>Hypoglycemia very common in children Mouthwash = 70% EtOH; perfumes and colognes = 40-60% EtOH Order serum EtOH level and glucose level; treat glucose level appropriately</td>
</tr>
<tr>
<td>Ethylene Glycol/ Methanol</td>
<td>Fomepizole (4-methylpyrazole) 15 mg/kg IV load over 30 min, then 10 mg/kg q12h OR Ethanol (10%) 10 mL/kg over 30 min, then 1.5 mL/h</td>
<td>CBC, electrolytes, glucose, ethanol level Consider hemodialysis</td>
</tr>
<tr>
<td>Heparin</td>
<td>Protamine sulfate 25-50 mg IV</td>
<td>For unfractionated heparin overdose only</td>
</tr>
<tr>
<td>Insulin IM/SC/ Oral Hypoglycemic</td>
<td>Glucose IV/PQ/NG tube Glucagon: 1-2 mg IM (if no access to glucose)</td>
<td>Glyburide carries highest risk of hypoglycemia among oral agents Consider octreotide for oral hypoglycemics (50-100 µg SC q6h) in these cases; consult local Poison Information Center</td>
</tr>
<tr>
<td>MDMA</td>
<td>Decontaminate (activated charcoal), supportive care</td>
<td>Monitor CK; treat rhabdomyolysis with high flow fluids: aggressive external cooling for hyperthermia</td>
</tr>
<tr>
<td>Opioids</td>
<td>See Universal Antidotes, ER48</td>
<td></td>
</tr>
<tr>
<td>TCAs</td>
<td>Decontaminate (activated charcoal) Aggressive supportive care NaHCO₃ bolus for wide QRS/seizures</td>
<td>Flumazenil antidote contraindicated in combined TCA and benzodiazepine overdose Also consider cardiac and hypertension support, seizure control Intralipid therapy (consult local Poison Information Center)</td>
</tr>
</tbody>
</table>

*Call local Poison Information Center for specific doses and treatment recommendations
Alcohol Related Emergencies

- see Psychiatry, PS18

Acute Intoxication
- slurred speech, CNS depression, disinhibition, lack of coordination
- nystagmus, diplopia, dysarthria, ataxia → may progress to coma
- hypotension (peripheral vasodilation)
- if obtunded, rule out
  - head trauma/intracranial hemorrhage
  - associated depressants/street drugs, toxic alcohols
  - may also contribute to respiratory/cardiac depression
  - hypoglycemia (screen with bedside glucometer)
  - hepatic encephalopathy: confusion, altered LOC, coma
  - precipitating factors: GI bleed, infection, sedation, electrolyte abnormalities, protein meal
  - Wernicke's encephalopathy (ataxia, ophthalmoplegia, delirium)
  - post-ictal state, basilar stroke

Withdrawal
- beware of withdrawal signs
- treatment
  - diazepam 10-20 mg IV/PO or lorazepam 2-4 mg IV/PO q1h until calm
  - frequency of dosing may have to be increased depending on clinical response
  - may use CIWA protocol and give benzodiazepines as above until CIWA < 10
  - thiamine 100 mg IM/IV then 50-100 mg/d
  - magnesium sulfate 4 g IV over 1-2 h (if hypomagnesemic)
  - admit patients with DT or multiple seizures

Table 31. Alcohol Withdrawal Signs

</tbody>
</table>

Cardiovascular Complications
- HTN
- cardiomyopathy: SOB, edema
- dysrhythmias (“holiday heart”)
  - AFib (most common), atrial flutter, SVT, VTach (especially Torsades if hypomagnesemic/ hypokalemic)

Metabolic Abnormalities
- alcoholic ketoacidosis
  - AG metabolic acidosis, urine ketones, low glucose, and normal osmolality
  - history of chronic alcohol intake with abrupt decrease/cessation
  - malnourished, abdominal pain with N/V
  - treatment: dextrose, thiamine (100 mg IM/IV prior to dextrose), volume repletion (with NS)
  - generally resolves in 12-24 h
- other alcohols
  - ethylene glycol → CNS, CVS, renal findings
  - methanol
    - early: lethargy, confusion
    - late: headache, visual changes, N/V, abdominal pain, tachypnea
  - both ethylene glycol and methanol produce severe metabolic acidosis with anion gap (as the alcohol is metabolized) and osmolar gap (initially after ingestion but before metabolism)
  - EtOH co-ingestion is protective
  - treatment
    - urgent hemodialysis required
    - fomepizole 15 mg/kg IV bolus OR EtOH 10% IV bolus and infusion to achieve blood level of 100 mg/dL (EtOH loading may be done PO)
• consider folic acid for methanol, and pyridoxine and thiamine for ethylene glycol – both help reduce conversion to active metabolites
• other abnormalities associated with alcohol: hypomagnesemia, hypophosphatemia, hypocalcemia, hypoglycemia, hypokalemia

Gastrointestinal Abnormalities
• gastritis
  • common cause of abdominal pain and GI bleed in chronic alcohol users
• pancreatitis
  • serum amylase very unreliable in patients with chronic pancreatitis, may need serum lipase
  • hemorrhagic form (15%) associated with increased mortality
  • fluid resuscitation very important
• hepatitis
  • AST/ALT ratio >2 suggests alcohol as the cause as well as elevated GGT with acute ingestion
• peritonitis/spontaneous bacterial peritonitis
  • leukocytosis, fever, generalized abdominal pain/tenderness
  • occasionally accompanies cirrhosis
  • paracentesis for diagnosis (common pathogens: E. coli, Klebsiella, Streptococcus)
• GI bleeds
  • most commonly gastritis or ulcers, even if patient known to have varices
  • consider Mallory-Weiss tear secondary to retching
  • often complicated by underlying coagulopathies
  • minor: treat with antacids
  • severe or recurrent: endoscopy

Disposition
• before patient leaves ED ensure stable vital signs, can walk unassisted, fully oriented
• offer social services to find shelter or detox program
• ensure patient can obtain any medications prescribed and can complete any necessary follow-up

Approach to the Overdose Patient

History
• age, weight, underlying medical problems, medications
• substance and how much
• time and symptoms since exposure determines prognosis and need for decontamination
• route
• intention, suicidality

Physical Exam
• focus on: ABCs, LOC/GCS, vitals, pupils

Disposition from the Emergency Department
• methanol, ethylene glycol
  • delayed onset, admit and watch clinical and biochemical markers
• TCAs
  • prolonged/delayed cardiotoxicity warrants admission to monitored (ICU) bed
  • if asymptomatic and no clinical signs of intoxication: 6 h ED observation adequate with proper decontamination and no ECG abnormalities
  • sinus tachycardia alone (most common finding) with history of OD warrants observation in ED
• hydrocarbons/smoke inhalation
  • pneumonitis may lag 6-8 h
  • consider observation for repeated clinical and radiographic examination
• ASA, acetaminophen
  • if borderline level, get second level 2-4 h after first
  • for ASA, must have at least 2 levels going down before discharge (3 levels minimum)
• oral hypoglycemics
  • admit all patients for minimum 24 h if hypoglycemic and 12 h after last octreotide dose
  • observe asymptomatic patient for at least 8 h

Psychiatric Consultation
• once patient medically cleared, arrange psychiatric intervention if required
• beware – suicidal ideation may not be expressed
Psychiatric Emergencies

Approach to Common Psychiatric Presentations

• see Psychiatry, PS2
• before seeing patient, ensure your own safety; have security/police available if necessary

History
• safety
  ▪ assess suicidality: suicidal ideation (SI), intent, plan, lethal means, and past attempts
  ▪ assess homicidality: homicidal ideation (HI), access to weapons, intended victim, and history of violence
  ▪ driving and children
  ▪ command hallucinations
• identify current stressors and coping strategies
• mood symptoms: manic, depressive
• anxiety: panic attacks, generalized anxiety, phobias, obsessive-compulsive disorder, post-traumatic stress disorder
• psychotic symptoms: delusions, hallucinations, disorganized speech, disorganized or catatonic behavior, negative symptoms (affective flattening, alogia, avolition)
• substance use history: most recent use, amount, previous withdrawal reactions
• past psychiatric history, medications, adherence with medications
• medical history: obtain collateral if available

Physical Exam
• complete physical exam focusing on: vitals, neurological exam, signs of head trauma, signs of drug toxicity, signs of metabolic disorder
• mental status exam: general appearance, behavior, cooperation, speech, mood and affect, thought content and form, perceptual disturbances, cognition (including MMSE if indicated), judgment, insight, reliability

Investigations
• investigations vary with age, established psychiatric diagnosis vs. first presentation, history and physical suggestive of organic cause
• as indicated: blood glucose, urine and serum toxicology screen, pregnancy test, electrolytes, TSH, AST/ALT, bilirubin, serum Cr, BUN, osmolality
• blood levels of psychiatric medications
• CT head if suspect neurological etiology
• LP if indicated

Acute Psychosis

Differential Diagnosis
• primary psychotic disorder (e.g. schizophrenia)
• secondary to medical condition (e.g. delirium)
• drugs: substance intoxication or withdrawal, medications (e.g. steroids, anticholinergics)
• infectious (CNS)
• metabolic (hypoglycemic, hepatic, renal, thyroid)
• structural (hemorrhage, neoplasm)

Management
• violence prevention
  ▪ remain calm, empathic, and reassuring
  ▪ ensure safety of staff and patients, have extra staff and/or security on hand
  ▪ patients demonstrating escalating agitation or overt violent behavior may require physical restraint and/or chemical tranquilization
• treat agitation: whenever possible, offer medication to patients as opposed to administering with force (helps calm and engage patient)
  ▪ benzodiazepines: lorazepam 2 mg PO/IM/SL
  ▪ antipsychotics: olanzapine 5 mg PO, haloperidol 5 mg PO/IM
• treat underlying medical condition
• psychiatry or Crisis Intervention Team consult
**Suicidal Patient**

**Epidemiology**
- attempted suicide F>M, completed suicide M>F
- second leading cause of death in people <24 yr

**Management**
- ensure patient safety: close observation, remove potentially dangerous objects from person and room
- assess thoughts (ideation), means, action (preparatory, practice attempts), previous attempts
- admit if there is evidence of intent and organized plan, access to lethal means, psychiatric disorder, intoxication (suicidal ideation may resolve with few days of abstinence)
- patient may require certification if unwilling to stay voluntarily
- do not start long-term medications in the ED
- psychiatry or Crisis Intervention Team consult

**Respiratory Distress**

- see *Pediatrics*, P89

**History and Physical Exam**
- infants not able to feed, older children not able to speak in full sentences
- anxious, irritable, lethargic – may indicate hypoxia
- tachypnea >60 (>40 if preschool age, >30 if school age), retractions, tracheal tug
  - see *Pediatrics*, P3 for age specific vital signs
- pulse paradoxus
- wheezing, grunting, vomiting

**In Pediatric Respiratory Distress, Must also Rule Out:**
- Anaphylaxis
- Foreign body
- Pneumonia
- Bronchiolitis
Management
- croup (usually laryngotracheitis caused by parainfluenza viruses)
  - humidified O₂ should not be given (no evidence for efficacy)
  - racemic epinephrine q1h x 3 doses, observe for 'rebound effects'
  - nebulized 1:1000 epi (racemic has limited availability)
  - dexamethasone x 1 dose
  - consider bacterial tracheitis/epiglottitis if unresponsive to croup therapy
- bacterial tracheitis
  - start croup therapy, but may have poor response
  - usually require intubation, ENT consult, ICU
  - start antibiotics (e.g., cloxacillin), pending C&S
  - epiglottitis
    - 4 D's: drooling, dyspnea, dysphagia, dysphonia + tripod sitting
    - do not examine oropharynx or agitate patient
    - immediate anesthesia, ENT call – intubate
    - then IV fluids, antibiotics, blood cultures
- asthma
  - supplemental O₂ if saturation <90% or PaO₂ <60%
  - bronchodilator therapy: salbutamol (Ventolin®) 0.15 mg/kg by masks q20min x 3
  - add 250–500 µg ipratropium (Atrovent®) to first 3 doses salbutamol
  - give corticosteroid therapy as soon as possible after arrival (prednisolone 2 mg/kg, dexamethasone 0.3 mg/kg)
  - if critically ill, not responding to inhaled bronchodilators or steroids: give IV bolus, then infusion of MgSO₄
  - IV β₂-agonists if critically ill and not responding to above

Febrile Infant and Febrile Seizures

FEBRILE INFANT
- see Pediatrics, P54
- for fever >100.4°F without obvious focus
  - <28 d
    - admit
    - full septic workup (CBC and differential, blood C&S, urine C&S, LP ± stool C&S, CXR if indicated)
    - treat empirically with broad spectrum IV antibiotics
  - 28-90 d
    - as above unless infant meets Rochester criteria (see sidebar), investigate as indicated by history and physical
  - >90 d
    - toxic: admit, treat, full septic workup
    - non-toxic and no focus: investigate as indicated by history and physical

FEBRILE SEIZURES
- see Pediatrics, P86

Etiology
- children aged 6 mo to 6 yr with fever or history of recent fever
- typical vs. atypical febrile seizures
- normal neurological exam afterward
- no evidence of intracranial infection or history of previous non-febrile seizures
- often positive family history of febrile seizures
- relatively well looking after seizure

Investigations and Management
- if it is a febrile seizure: treat fever and look for source of fever
- if not a febrile seizure: treat seizure and look for source of seizure
- note: may also have fever but may not meet criteria for febrile seizure
- ± EEG (especially if first seizure), head U/S (if fontanelle open)

</tbody>
</table>
Child Abuse and Neglect

- see *Pediatrics*, P14
- obligation to report any suspected/known case of child abuse or neglect to CAS yourself (do not delegate)
- document injuries
- consider skeletal survey x-rays (especially in non-ambulatory child), ophthalmology consult, CT head
- injury patterns associated with child abuse
  - HI: torn frenulum, dental injuries, bilateral black eyes, traumatic hair loss, diffuse severe CNS injury, retinal hemorrhage
  - Shaken Baby Syndrome: diffuse brain injury, subdural/SAH, retinal hemorrhage, minimal/no evidence of external trauma, associated bony fractures
  - skin injuries: bites, bruises/burns in shape of an object, glove/stocking distribution of burns, bruises of various ages, bruises in protected areas
  - bone injuries: rib fractures without major trauma, femur fractures age <1 yr, spiral fractures of long bones in non-ambulatory children, metaphyseal fractures in infants, multiple fractures of various ages, complex/multiple skull fractures
  - GU/GI injuries: chronic abdominal/perineal pain, injury to genitals/rectum, STD/pregnancy, recurrent vomiting or diarrhea

Basic Anatomy Review

Major Endocrine Organs

**HYPOTHALAMUS**
- Corticotropin-RH (CRH)
- Gonadotropin-RH (GnRH)
- Thyrotropin-RH (TSH)
- Growth hormone-RH (GHRH)
- Antidiuretic hormone (ADH)*
- Oxytocin*

**THYROID GLAND**
- Triiodothyronine (T3)
- Thyroxine (T4)

**ADRENAL GLAND**
- Cortex
  - Aldosterone
  - Cortisol
  - Androgens
  - Medulla
  - Catecholamines

**PARATHYROID GLANDS**
- Parathyroid hormone (PTH)

**TESTES**
- Testosterone

**PITUITARY GLAND**
- Anterior pituitary
  - Growth hormone (GH)
  - Prolactin (PRL)
  - Thyroid-stimulating hormone (TSH)
  - Luteinizing hormone (LH)
  - Follicle-stimulating hormone (FSH)
- Posterior pituitary
  - Antidiuretic hormone (ADH)*
  - Oxytocin*

**PARATHYROID GLANDS**
- Parathyroid hormone (PTH)

**PANCREAS**
- Insulin
- Glucagon
- Estrogen
- Progestosterone

**OVARIYES**
- Estrogen
- Progestosterone

**GENERAL FUNCTION OF ORGANS**

The Hypothalamic-Pituitary Axis
Information about cortical inputs, automatic function, environmental cues (light, temperature) and peripheral hormonal feedback is synthesized at the coordinating center of the endocrine system, the hypothalamus. The hypothalamus then sends signals to the pituitary to release hormones that affect the thyroid, adrenals, gonads, growth, milk production, and water balance.

**Anatomy ↔ Function**

Hypothalamic hormones: small peptides, non-binding protein → rapid degradation
- High [] in pituitary-portal blood system
- Low [ ] in peripheral circulation

Proximity of axis preserves the pulsatile output signals from the hypothalamic neurons.

**Thyroid**
Thyroid hormone is critical to 1) brain and somatic development in fetus and infants, 2) metabolic activity in adults, and 3) function of virtually every organ system.

**Adrenal**
Each gland, 6-8 g, has 1) a cortex with 3 layers that act like independent organs ( zona glomerulosa → aldosterone, fasciculata → cortisol, reticularis → androgen and estrogen precursors), and 2) a medulla that acts like a sympathetic ganglion to store/synthesize adrenaline and noradrenaline.

**Gonads**
Bifunctional: sex steroid synthesis and gamete production.

Sex steroids control sexuality and affect metabolic and brain functions.

**Parathyroid**
Synthesize and secrete PTH, a principle regulator of ECF Ca^2+ regulated by [Ca^2+]_i, Mg^2+ and 1,25(OH)2D (active metabolite of vit D), and phosphate.

**Pancreas**
Endocrine islet β-cells produce insulin: oppose glucose production (glycogenolysis, gluconeogenesis), increase glucose uptake into muscle and fat. Glucagon, epinephrine, cortisol, and GH are counterregulatory.

**Dyslipidemias**

**Definition**
- Metabolic disorders characterized by elevations of fasting plasma LDL-cholesterol, and/or triglycerides (TG), and/or low HDL-cholesterol

**Overview of Lipid Transport**
- Lipoproteins are spherical complexes that consist of a lipid core surrounded by a shell of water-soluble cholesterol, apoproteins, and phospholipids
- Lipoproteins transport lipids within the body
- Apolipoproteins serve as enzyme co-factors, promote clearance of the particle by interacting with cellular receptors, and stabilize the lipoprotein micelle

<td>↑ LDL ↑ TC</td>
<td>• Tendinous xanthomatosis (Achilles, patellar, and extensor tendons of hand) • Arcus cornealis • Xanthelasma • Heterozygotes: premature CAD, 50% risk of MI in men by age 30 • Homozygotes: manifest CAD and other vascular disease early in childhood and can be fatal (&lt;20 yr) if untreated</td>
<td>• Homozygotes: improvement of LDL with HMG-CoA reductase inhibitors, often in combination with niacin, ezetimibe, or bile acid sequestrants • Homozygotes: partial control with portacaval shunt or LDL apheresis in conjunction with niacin; large dose atorvastatin is modestly effective</td>
</tr>
</tbody>
</table>

| Polygenic Hypercholesterolemia | • Few mild inherited defects in cholesterol metabolism | ↑ TC ↑ LDL | • Asymptomatic until vascular disease develops • No xanthomata | • HMG-CoA reductase inhibitors, ezetimibe, niacin, bile acid sequestrant |
SECONDARY HYPERCHOLESTEROLEMIA

**Etiology**
- endocrine: hypothyroidism
- renal: nephrotic syndrome
- immunologic: monoclonal gammopathy
- hepatic: cholestatic liver disease (e.g. primary biliary cirrhosis)
- nutritional: diet, anorexia nervosa
- drugs: cyclosporin, anabolic steroids, carbamazepine

Hypertriglyceridemia (Elevated Triglycerides)

### PRIMARY HYPERTRIGLYCERIDEMIA

<td>Decrease dietary simple carbohydrates and fat intake</td>
</tr>
</tbody>
</table>

### SECONDARY HYPERTRIGLYCERIDEMIA

**Etiology**
- endocrine: obesity/metabolic syndrome, hypothyroidism (more for high LDL, not TG), acromegaly, Cushing’s syndrome, DM
- renal: chronic renal failure, polyclonal and monoclonal hypergammaglobulinemia
- hepatic: chronic liver disease, hepatitis, glycogen storage disease
- drugs: alcohol, corticosteroids, estrogen, hydrochlorothiazide, retinoic acid, β-blockers without intrinsic sympathomimetic action (ISA), anti-retroviral drugs, atypical antipsychotics, oral contraceptive pills
- other: pregnancy

Combined Hyperlipidemia

Dyslipidemia and the Risk for Coronary Artery Disease

- increased LDL is a major risk factor for atherosclerosis and CAD as LDL is the major atherogenic lipid particle
- increased HDL is associated with decreased cardiovascular disease and mortality
- moderate hypertriglyceridemia (triglyceride level 2.3-9 mmol/L) is an independent risk factor for CAD, especially in people with DM and in post-menopausal women
- treatment of hypertriglyceridemia has not been shown to reduce CAD risk
Screening
• screen men over age 40, women over age 50, or post-menopausal
• if following risk factors present, screen at any age
  ▫ DM
  ▫ cigarette smoking
  ▫ HTN (sBP >140, dBP >90)
  ▫ obesity
  ▫ family history of premature CAD
  ▫ clinical signs of hyperlipidemia (xanthelasma, xanthoma, arcus cornealis)
  ▫ evidence of atherosclerosis
  ▫ rheumatoid arthritis, SLE, psoriasis
  ▫ HIV infection on highly active antiretroviral therapy (HAART)
  ▫ chronic kidney disease (estimated GFR <60 mL/min/1.73 m²)
  ▫ erectile dysfunction
• screen children with a family history of hypercholesterolemia or chylomicronemia

Factors Affecting Risk Assessment
• metabolic syndrome
• apolipoprotein B (apo B)
  ▫ each atherogenic particle (VLDL, IDL, LDL, and lipoprotein A) contains one molecule of apo B
  ▫ serum [apo B] reflects the total number of particles and may be useful in assessing cardiovascular risk and adequacy of treatment in high risk patients and those with metabolic syndrome
• C-reactive protein (hs-CRP) levels
  ▫ highly sensitive acute phase reactant
  ▫ may be clinically useful in identifying those at a higher risk of cardiovascular disease than predicted by the global risk assessment

Treatment of Dyslipidemias

Approach to Treatment
For clinical guidelines see National Institutes of Health; Adult Treatment Panel III https://www.nhlbi.nih.gov/guidelines/cholesterol/atglance.pdf
• determine lipoprotein levels – obtain complete profile after 9 to 12 h fast
• identify presence of of clinical atherosclerotic disease that confers high risk for CHD events
• If 2+ risk factors (other than LDL) are present without CHD or CHD risk equivalent estimate 10 yr risk of CAD using Framingham model
• establish treatment targets according to level of risk

Table 5. LDL Cholesterol Goals and Cutpoints for Therapeutic Lifestyle Changes (TLC)

Treatment Effect
Each 40 mg/dL (1.0 mmol/L) decrease in LDL corresponds to 20–25% relative risk reduction in cardiovascular disease

For Statin Follow-Up
• Liver enzymes and lipid profile: liver enzymes measured at the beginning of treatment then once after therapy initiated; lipids (once stabilized) measured annually; order both if patient complains of jaundice, RUQ pain, dark urine
• CK at baseline and if patient complains of myalgia
• D/C statin if CK >10x upper limit of normal or patient has persistent myalgia

Intensive Lipid Lowering in CAD: TNT
NEJM 2005;352:1425-1435
Study: Multicenter, randomized, double-blinded trial with median follow-up of 4.9 yr.
Patients: 10,001 patients with CAD and LDL-C <3.4 mmol/L (<131.5 mg/dL)
Intervention: 80 mg vs. 10 mg atorvastatin daily.
Main Outcomes: Death from CAD, MI, cardiac arrest, or stroke.
Results: A primary event occurred in 8.7% of the patients receiving intensive therapy, compared to 10.5% of patients receiving standard therapy (HR 0.78, p<0.001). There was no difference in overall mortality. Incidence of persistent transaminase elevations was higher in the intensive therapy group (1.2% vs. 0.2%, p<0.001).
Conclusion: Intensive statin therapy is associated with lower rates of CAD events than standard therapy, but also a higher rate of transaminase elevation.

Simvastatin to Lower CAD Risk – The Heart Protection Study (HPS)
Lancet 2002;360:7-22
Study: Randomized, double-blind, placebo-controlled trial with median follow-up of 5.9 yr.
Patients: 20,536 patients with coronary disease, other occlusive arterial disease or diabetes (aged 40-80 yr) who had a total cholesterol level of ≥3.5 mmol/L
Intervention: Simvastatin 40 mg/d or placebo.
Main Outcomes: Mortality, fatal or non-fatal vascular events.
Results: The use of simvastatin significantly decreased total mortality (12.9 vs. 14.7, p=0.0003) and the first event rate of any cardiovascular event by 25% (p<0.001).
Conclusion: Treatment with simvastatin improved survival and cardiovascular outcomes in high-risk CAD patients.
Overview of Glucose Regulation

Pre-Diabetes (Impaired Glucose Tolerance/Impaired Fasting Glucose)

- 1-5% per yr go on to develop DM
- 50-80% revert to normal glucose tolerance
- weight loss may improve glucose tolerance
- increased risk of developing macrovascular complications
- lifestyle modifications decrease progression to DM by 58%

Diagnostic Criteria
- impaired fasting glucose (IFG): fasting blood glucose (FBG) 110-125 mg/dL (6.1-6.9 mmol/L)
- impaired glucose tolerance (IGT): 2h 75 g oral glucose tolerance test (OGTT) 140-200 mg/dL (7.8-11.0 mmol/L)

Diabetes Mellitus

Definition
- syndrome of disordered metabolism and inappropriate hyperglycemia secondary to an absolute/relative deficiency of insulin, or a reduction in biological effectiveness of insulin, or both

Diagnostic Criteria
- any one of the following is diagnostic
  - presence of classic symptoms of DM (polyuria, polydipsia, polyphagia, weight loss, blurry vision, nocturia, ketonuria) PLUS random blood glucose (BG) ≥ 200 mg/dL (11.1 mmol/L)
  - on at least two separate occasions
    - FPG ≥ 126 mg/dL (7.0 mmol/L) (fasting = no caloric intake for at least 8 h) OR
    - 2 h 75 g OGTT ≥200 mg/dL (11.1 mmol/L) OR
    - random PG ≥200 mg/dL (11.1 mmol/L) OR
    - HbA1c ≥6.5%

Glucose Related Emergencies
- DKA
- HHS
- Hypoglycemia
Etiology and Pathophysiology

Table 7. Etiologic Classification of Diabetes Mellitus

| I. Type 1 DM (immune-mediated β cell destruction, usually leading to absolute insulin deficiency) |
| II. Type 2 DM (ranges from predominantly insulin resistance with relative insulin deficiency to a predominantly insulin secretory defect with insulin resistance 2nd to β cell dysfunction) |
| III. Other specific causes of DM: |
| a. Genetic defects of β cell function (e.g., MODY – Maturity-Onset Diabetes of the Young) or insulin action |
| b. Diseases of the exocrine pancreas: |
| • Pancreatitis, pancreactectomy, neoplasia, cystic fibrosis, hemochromatosis ("bronze diabetes") |
| c. Endocrinopathies: |
| • Acromegaly, Cushing’s syndrome, glucagonoma, pheochromocytoma, hyperthyroidism |
| d. Drug-induced: |
| • Glucocorticoids, thyroid hormone, β-adrenergic agonists, thiazides, phenytoin, clozapine |
| e. Infections: |
| • Congenital rubella, CMV, coxsackie |
| f. Genetic syndromes associated with DM: |
| • Down’s syndrome, Klinefelter’s syndrome, Turner’s syndrome |

IV. Gestational Diabetes Mellitus (see Obstetrics, OB13)

<td></td>
<td></td>
</tr>
</tbody>
</table>

Epidemiology

| More common in Caucasians |
| Less common in Asians, Hispanics, Aboriginals, and Blacks |
| Accounts for 5-10% of all DM |

Etiology

| Autoimmune |
| Complex and multifactorial |

Genetics

| Monozygotic twin concordance is 30-40% |
| Associated with HLA class II DR3 and DR4, with either allele present in up to 95% of type 1 DM |
| Certain DQ alleles also confer a risk |

Pathophysiology

| Synergistic effects of genetic, immune, and environmental factors that cause β cell destruction resulting in impaired insulin secretion |
| Autoimmune process is believed to be triggered by environmental factors (e.g., viruses, bovine milk protein, urea compounds) |
| Pancreatic cells are infiltrated with lymphocytes resulting in islet cell destruction |
| 80% of β cell mass is destroyed before features of DM present |

Natural History

- After initial presentation, honeymoon period often occurs where glycemic control can be achieved with little or no insulin treatment as residual cells are still able to produce insulin
- Once these cells are destroyed, there is complete insulin deficiency

Circulating Autoantibodies

| Islet cell Ab present in up to 60-85% |
| Most common islet cell Ab is against glutamic acid decarboxylase (GAD) |
| Up to 60% have Ab against insulin |

<10%

Blood Glucose Control in Type 2 DM – UKPDS 33

Lancet 1998;352:837-853

Study: Randomized controlled trial (mean follow-up 10 yr).

Patients: 3,867 patients with newly diagnosed type 2 DM (mean age 53 yr, 61% men, 81% white, mean fasting plasma glucose [FPG] 6.1-15.0 mmol/L (<236 mg/dL) – 236 mg/dL) without hyperglycemic symptoms.

Exclusions included severe cardiovascular disease, renal disease, retinopathy, and others.

Intervention: Intensive treatment with a sulfonylurea or insulin (target FPG <6 mmol/L (<222 mg/dL)) vs. conventional treatment with diet alone (target FPG <7 mmol/L (<126 mg/dL)).

Main Outcomes: DM-related endpoints (MI, angina, heart failure, stroke, renal failure, amputation, retinopathy, blindness, death from hyperglycemia or hypoglycemia), DM-related death, and all-cause mortality.

Results: Patients allocated to intensive treatment had lower median HbA1c levels (p<0.001).

<table>
<thead>
<tr>
<th>Outcome</th>
<th>RRR (p value)</th>
</tr>
</thead>
<tbody>
<tr>
<td>DM-related endpoint</td>
<td>12 (0.029)</td>
</tr>
<tr>
<td>DM-related death</td>
<td>10 (0.34)</td>
</tr>
<tr>
<td>All-cause mortality</td>
<td>6 (0.44)</td>
</tr>
</tbody>
</table>

Patients allocated to intensive therapy had less hypoglycemic episodes and greater weight gain.

Conclusion: Intensive blood glucose control reduces microvascular, but not macrovascular complications in type 2 DM.

</table>

Glycemic Targets

- HbA1c reflects glycemic control over 3 mo and is a measure of patient’s long-term DM control.
- Therapy in most individuals with type 1 or type 2 DM should be targeted to achieve a HbA1c ≤7.0% in order to reduce the risk of microvascular and if implemented early in the course of disease, macrovascular complications.
- More intensive glucose control, HbA1c <6.5%, may be targeted in patients with a shorter duration of DM with no evidence of significant CVD and longer life expectancy, to further reduce risk of nephropathy and retinopathy, provided this does not result in a significant increase in hypoglycemia.
- Less stringent HbA1c targets (7.1-8.5%) may be more appropriate in type 1 and type 2 patients with limited life expectancy, higher level of functional dependency, a history of recurrent severe hypoglycemia, multiple comorbidities, extensive CAD, or a failure to attain HbA1c <7.0% despite treatment intensification.
- There may be harm associated with strategy to target HbA1c <6.0% in certain patients with type 2 DM (see ACCORD trial, E9).

Diet

- Daily carbohydrate intake 45-60% of energy, protein 15-20% of energy, and fat <35% of energy.
- Intake of saturated fats <7% and polyunsaturated fats <10% of total calories each.
- Limit sodium, alcohol, and caffeine intake.
- Type 1: Carbohydrate counting is used to titrate insulin regimen.
- Type 2: Weight reduction.

Lifestyle

- Regular physical exercise to improve insulin sensitivity, lower lipid concentrations and control blood pressure.
- Smoking cessation.

Medical Treatment: Oral Antihyperglycemic Agents and/or Incretin Therapy (Type 2 DM)

- Initiate oral antihyperglycemic therapy and/or incretin therapy within 2-3 mo if lifestyle management does not result in glycemic control.
- If HbA1c >8.5%, initiate pharmacologic therapy immediately and consider combination oral therapy or insulin immediately.
- See Common Medications, E52 for details on antihyperglycemic agents.

Medical Treatment: Insulin (Figure 5)

- Used for type 1 DM at onset, may be used in type 2 DM at any point in treatment.
- Routes of administration: subcutaneous injections, continuous subcutaneous insulin infusion pump, IV infusion (regular insulin only).
- Bolus insulins: short-acting (Insulin regular), rapid-acting analogue (Insulin aspart, Insulin lispro, Insulin glulisine).
- Basal insulins: intermediate-acting (Insulin NPH), long-acting analogue (Insulin detemir, Insulin glargine).

Cardiovascular Effects of Intensive Lifestyle Intervention in Type 2 DM: the Look AHEAD Trial (2013;365:193-200)

- Study: RCT with 8.6 yr of median follow-up.
- Population: 5,145 overweight or obese patients with type 2 DM.
- Intervention: Intensive lifestyle intervention promoting weight loss through decreased caloric intake and increased physical activity (intervention) or diabetes support and education (control).
- Primary Outcome: First occurrence of death from cardiovascular (CV) causes, non-fatal myocardial infarction, non-fatal stroke, or hospitalization for angina.
- Results: There was no significant difference between intensive and conventional glycemic control for all-cause mortality or cardiovascular mortality. Targeting intensive glycemic control reduced the risk of any coronary event, the composite risk of microvascular disease, nephropathy, retinal photocoagulation, and nephropathy. The risks of both mild and severe hypoglycemia were increased with targeting intensive glycemic control.
- Conclusions: Intensive glycemic control did not reduce all-cause mortality and cardiovascular mortality compared to conventional glycemic control. Intensive glycemic control reduced the risk of microvascular complications while increasing the risk of hypoglycemia. Intensive glycemic control may also reduce the risk of non-fatal MI in trials exclusively dealing with glycemic control in usual care settings.

**Effects of Intensive Glucose Lowering in Type 2 DM: The ACCORD Trial**
NEJM 2010;362:1563-1574

**Study:** Multicenter RCT.

**Patients:** 10,251 patients (mean age 62.2) with type 2 DM, and cardiovascular risk factors.

**Intervention:** Intensive therapy targeting a HbA1c level of less than 6.0% or standard therapy targeting 7.0 to 7.9%.

**Outcomes:** First occurrence of nonfatal MI, nonfatal stroke, or death from CV causes.

**Results:** The intensive therapy arm was stopped early (3.5 yr vs. 5.6 yr planned) due to evidence of increased mortality. There was no difference in primary outcome for either study arm. There was a significant increase in all-cause mortality, CV mortality, nonfatal MI, and CHF in the intensive therapy group. There were increased rates of all hyperglycemic events, any nonhemodynamic serious adverse events, fluid retention, and weight gain >10 kg, but lower systolic and diastolic blood pressure in the intensive therapy group. There was an increased incidence of elevated ALT (1–3 times upper limit) and ACE drug use in the standard therapy group.

**Conclusions:** Intensive glucose lowering therapy in type 2 DM does not improve clinic outcomes and actually increases the risk of mortality with more adverse events compared to standard therapy.

Additional research is required to discern the cause.

---

**Effects of Intensive Blood Pressure Control in Type 2 DM: The ACCORD Trial**
NEJM 2010;362:1575-1585

**Study:** RCT, unblinded with 4.7 yr of mean follow-up.

**Population:** 4,733 patients with type 2 DM, risk factors for cardiovascular (CV) disease, systolic blood pressure (SBP) between 130-180 mmHg.

**Intervention:** DBP control less than 120 mmHg (intensive) or 140 mmHg (standard).

**Primary Outcomes:** Major CV event (composite nonfatal MI, nonfatal stroke, or CV-related death).

**Results:** Mean number of medications at 1 yr for intensive therapy was 3.4 (95% CI 3.3-4.5) vs. 2.1 (95% CI 2.1-2.2) for standard therapy. There was a significant increase in all serious adverse events in the intensive treatment arm (3.3% vs. 1.27%, p<0.001); especially bradycardia or arrhythmia (0.5% vs. 0.1%, p<0.002) and hyperkalemia (0.4% vs. 0.04%, p=0.01). There was no significant difference in primary outcomes in the two study arms, or all-cause mortality. There was a significant reduction in any stroke (0.22%/yr vs. 0.53%/yr, p<0.001) and nonfatal stroke incidence (0.30%/yr vs. 0.47%/yr, p=0.03) in the intensive therapy arm.

**Conclusions:** Intensive BP lowering to less than 120 mmHg vs. 140 mmHg in patients with type 2 DM and CV risk factors does not reduce major CV event risk reduction except for stroke events.

---

**Effects of Combination Lipid Therapy in Type 2 DM: The ACCORD Trial**
NEJM 2010;362:1583-1594

**Study:** RCT, double-blinded trial with 4.7 yr of mean follow-up.

**Population:** 5,518 patients with type 2 DM.

**Intervention:** Statin with or without fibrate therapy.

**Primary Outcome:** Major CV event (composite nonfatal MI, nonfatal stroke, or CV-related death).

**Results:** No significant differences in primary outcome between the two arms. No difference in all MI, all stroke, or all-cause mortality by study arms.

**Conclusions:** The addition of fibrate therapy to statin therapy in patients with type 2 DM does not reduce major CV event risk.
Insulin Regimens

Table 10. Insulin Regimens for Type 2 DM and Type 1 DM

Variable Insulin Dose Schedule (“Sliding/Supplemental/Correction Scale”)

- for patients on Basal-Bolus MDI regimen: patient takes usual doses of basal insulin but varies doses of bolus insulin based on BG reading at time of dose
- use baseline bolus insulin dose when within BG target range; add or subtract units when above or below target
- when used in hospital (including perioperative management of DM) patient should also receive basal insulin to prevent fluctuations in blood sugar levels or long periods of hyperglycemia without intervention
- construction of a supplemental sliding scale for a patient on anti-hyperglycemics
  - Correction Factor (CF) = 100/Total Daily Dose of insulin (TDD)
  - BG <4: call MD and give 15 g carbohydrates
  - BG between 4 to 8: no additional insulin
  - BG between 8 to (8 + CF): give one additional unit
  - BG between (8 + CF) to (8 + 2CF): give two additional units
  - BG between (8 + 2CF) to (8 + 3CF): give three additional units

Insulin Pump Therapy (continuous subcutaneous insulin infusion [CSII])

- external battery-operated device provides constant basal dose of rapid-acting insulin analogue (aspart, glulisine, or lispro) through small subcutaneous catheter
- at meals, patient programs pump to deliver insulin bolus
- provides improved quality of life and flexibility
- risk of DKA if pump is inadvertently disconnected

</tbody>
</table>
Macrovascular Complications

- increased risk of CAD, ischemic stroke, and peripheral arterial disease secondary to accelerated atherosclerosis
- CAD (see Cardiology and Cardiac Surgery, C25)
  - risk of MI is 3–5x higher in those with DM compared to age-matched controls
  - CAD is the leading cause of death in type 2 DM
  - most patients with DM are considered “high risk” under the risk stratification for CAD (see Dyslipidemias, E2)
- ischemic stroke (see Neurology, N46)
  - risk of stroke is approximately 2.5x higher in those with DM
  - level of glycemia is both a risk factor for stroke and a predictor of a poorer outcome in patients who suffer a stroke
  - HbA1c level is a significant and independent predictor of the risk of stroke
- peripheral arterial disease (see Vascular Surgery, VS2)
  - manifested by intermittent claudication in lower extremities, intestinal angina, foot ulceration
  - risk of foot gangrene is 30x higher in those with DM compared to age-matched controls
  - risk of lower extremity amputation is 15x higher in those with DM
- treatment
  - tight blood pressure control (<130/80 mmHg); especially for stroke prevention
  - tight glycemic control in early DM without established CVD (refer to ACCORD, VADT, ADVANCE, DCCT, EDIC, UKPDS extension studies)
  - tight low density lipoprotein (LDL) cholesterol control (LDL <77 mg/dL [<2.0 mmol/L])
  - ACEI or angiotensin receptor blocker in high-risk patients
  - tight blood pressure control (<130/80 mmHg); especially for stroke prevention
  - smoking cessation

Microvascular Complications

DIABETIC RETINOPATHY (see Ophthalmology, OP35)

Epidemiology

- type 1 DM: 25% affected at 5 yr, 100% at 20 yr
- type 2 DM: 25% affected at diagnosis, 60% between 20 yr
- leading cause of blindness in North America between the ages of 20–74
- most important factor is disease duration

Clinical Features

- nonproliferative
  - asymptomatic but if macular involvement occurs vision may be impaired
  - microaneurysms, hard exudates, dot-blot and flame hemorrhages
- preproliferative
  - macular edema, cotton wool spots, venous shunts and beading, intra-retinal microvascular abnormalities (IRMA)
- proliferative
  - with neovascularization and fibrous scarring; great risk for loss of vision secondary to vitreous hemorrhage (floaters) and/or retinal detachment

Treatment and Prevention

- tight glycemic control (delays onset, decreases progression), tight lipid control, manage HTN, smoking cessation
- pan-retinal laser photocoagulation for treatment of neovascularization
- vitrectomy
- annual follow-up visits with an optometrist or ophthalmologist examination through dilated pupils whether symptomatic or not (immediate referral after diagnosis of type 2 DM; 5 yr after diagnosis of type 1 DM)
- interval for follow-up should be tailored to severity of retinopathy
DIABETIC NEPHROPATHY (see Nephrology, NP28)

Epidemiology
- DM-induced renal failure is the most common cause of renal failure in North America
- 20-40% of persons with type 1 DM (after 5-10 yr) and 4-20% with type 2 DM have progressive nephropathy

Pathophysiology
- thickening of capillary basement membrane and glomerular mesangium resulting in glomerulosclerosis and renal insufficiency
- diffuse glomerulosclerosis is more common than nodular intercapillary glomerulosclerosis (Kimmelstiel-Wilson lesions)

Screening
- serum creatinine
- random urine test for albumin to creatinine ratio (ACR) plus urine dipstick test for all type 2 DM patients at diagnosis, then annually, and for postpubertal type 1 DM patients with ≥5 yr duration of DM

Clinical Features
- initial changes include microalbuminuria, increased GFR (up to 140%) from hyperfiltration, enlarged kidneys
- microalbuminuria: 30 μg/mg
- macroalbuminuria: 300 μg/mg
- progression over 15 yr to cause HTN, persistent proteinuria (macroalbuminuria), nephrotic syndrome, and renal failure
- elevated HbA1c is an independent risk factor for progression to microalbuminuria

Treatment and Prevention
- tight glycemic control
- tight blood pressure control (<130/80 mmHg): can use either ACEI or ARB (often used first line for their CVD protection)
- even in the absence of glycemic control ACEIs or ARBs reduce the level of albuminuria and the rate of progression of renal disease in normotensive and hypertensive patients with type 1 or type 2 DM
- type 1 DM → CKD with either HTN or albuminuria → ACEIs 1st line; ARBs 2nd line
- type 2 DM → CKD with HTN and albuminuria → ACEIs or ARBs (dose adjust if creatinine clearance (CrCl) <60 mL/min)
- consider use of non-dihydropyridine calcium channel blocker (e.g. diltiazem) in those unable to tolerate both ACEIs and ARBs
- limit use of nephrotoxic drugs and dyes
- renal failure may necessitate hemodialysis and renal transplant

DIABETIC NEUROPATHY (see Neurology, N42)

Epidemiology
- approximately 50% of patients within 10 yr of onset of type 1 DM and type 2 DM

Pathophysiology
- can have peripheral sensory neuropathy, motor neuropathy, or autonomic neuropathy
- mechanism poorly understood
- acute cranial nerve palsies and diabetic amyotrophy are thought to be due to ischemic infarction of peripheral nerve
- the more common motor and sensory neuropathies are thought to be related to metabolic or osmotic toxicity secondary to increased sorbitol and/or decreased myoinositol (possible mechanisms include accumulation of advanced glycation endproducts [AGE], oxidative stress, protein kinase C, nerve growth factor deficiency)

Screening
- 128 Hz tuning fork or 10 g monofilament at diagnosis and annually in people with type 2 DM and after 5 yr duration of type 1 DM

Management of Diabetic Retinopathy: A Systematic Review
JAMA 2007;298:902-916

Purpose: To review the best evidence for primary and secondary interventions in the management of diabetic retinopathy (DR), including diabetic macular edema.

Study Selection: English-language RCTs with more than 12 mo of follow-up and meta-analyses were included.

Results: Forty-four studies (including 3 meta-analyses) met the inclusion criteria. Tight glycemic and blood pressure control reduces the incidence and progression of DR. Pan-retinal laser photocoagulation reduces the risk of moderate and severe visual loss by 50% in patients with severe nonproliferative and proliferative retinopathy. Focal laser photocoagulation reduces the risk of moderate visual loss by 50-70% in eyes with macular edema. Early vitrectomy improves visual recovery in patients with proliferative retinopathy and severe vitreous hemorrhage. Intravitreal injections of steroids may be considered in eyes with persistent loss of vision when conventional treatment has failed.

Conclusions: Tight glycemic and blood pressure control remains the cornerstone in the primary prevention of DR. Pan-retinal and focal retinal laser photocoagulation reduces the risk of visual loss in patients with severe DR and macular edema, respectively. There is currently insufficient evidence to recommend routine use of other treatments.
Clinical Features

Table 13. Clinical Presentation of Diabetic Neuropathies

<table>
<thead>
<tr>
<th>Peripheral Sensory Neuropathy</th>
<th>Motor Neuropathy</th>
<th>Autonomic Neuropathy</th>
</tr>
</thead>
<tbody>
<tr>
<td>Paresthesias (tingling, itching), neuropathic pain, radicular pain, numbness, decreased tactile sensation</td>
<td>Less common than sensory neuropathy</td>
<td>Postural hypotension, tachycardia, decreased cardiovascular response to Valsalva maneuver</td>
</tr>
<tr>
<td>Blateral and symmetric with decreased perception of vibration and pain/temperature; especially true in the lower extremities but may also be present in the hands</td>
<td>Delayed motor nerve conduction and muscle weakness/atrophy</td>
<td>Gas troparexis and alternating diarrhea and constipation</td>
</tr>
<tr>
<td>Decreased ankle reflex</td>
<td>May involve one nerve trunk (mononeuropathy) or more (mononeuritis multiplex)</td>
<td>Urinary retention and erectile dysfunction</td>
</tr>
<tr>
<td>Symptoms may first occur in entrapment syndromes e.g. carpal tunnel</td>
<td>Some of the motor neuropathies spontaneously resolve after 6-8 wk</td>
<td></td>
</tr>
<tr>
<td>May result in neuropathic ulceration of foot</td>
<td>Reversible CN palsies: III (ptosis/ophthalmoplegia, pupil sparing), VI (inability to laterally deviate eye), and VII (Bell’s palsy)</td>
<td></td>
</tr>
<tr>
<td>Diabetic amyotrophy: refers to pain, weakness, and wasting of hip flexors or extensors</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Treatment and Management

- tight glycemic control
- for neuropathic pain syndromes: tricyclic antidepressants (e.g. amitriptyline), pregabalin, duloxetine, anti-epileptics (e.g. carbamazepine, gabapentin), and capsaicin
- foot care education
- Jobst® fitted stocking and tilting of head of bed may decrease symptoms of orthostatic hypotension
- treat gastroparesis with domperidone and/or metoclopramide (dopamine antagonists), erythromycin (stimulates motilin receptors)
- medical, mechanical, and surgical treatment for erectile dysfunction (see Urology, U30)

Other Complications

Dermatologic

- diabetic dermopathy: atrophic brown spots commonly in pretibial region known as “shin spots”, secondary to increased glycosylation of tissue proteins or vasculopathy
- eruptive xanthomas secondary to increased triglycerides
- necrobiosis lipoidica diabeticorum: rare complication characterized by thinning skin over the shins allowing visualization of subcutaneous vessels

Bone and Joint Disease

- juvenile cheiroarthropathy: chronic stiffness of hand caused by contracture of skin over joints secondary to glycosylated collagen and other connective tissue proteins
- Dupuytren’s contracture
- bone demineralization: bone density 10-20% below normal
- adhesive capsulitis (“frozen shoulder”)

Cataracts

- subcapsular and senile cataracts secondary to glycosylated lens protein or increased sorbitol causing osmotic change and fibrosis

Infections

- see Infectious Diseases, ID16

Hypoglycemia

Etiology and Pathophysiology

- hypoglycemia occurs most frequently in people with DM receiving insulin or certain antihyperglycemic therapies (insulin secretagogues)
- in people without DM, care must be taken to distinguish fasting from post-prandial hypoglycemia as each invokes separate differential diagnoses

Effects of Treatments for Symptoms of Painful Diabetic Neuropathy: Systematic Review

**Purpose:** To evaluate the effects of treatments for the symptoms of painful diabetic neuropathy.

**Study Selection:** RCTs comparing topically applied and orally administered drugs with a placebo in adults with painful diabetic neuropathy.

**Results:** 25 included reports compared anticonvulsants (n=1,270), antidepressants (94), opioids (329), ion channel blockers (173), NMDA antagonist (14), duloxetine (65), capsaicin (277), and isosorbide dinitrate spray (22) with placebo. The odds ratios in terms of 50% pain relief were 5.33 (95% CI 1.77-16.02) for traditional anticonvulsants, 3.25 (95% CI 2.27-4.68) for newer generation anticonvulsants, and 2.24 (95% CI 9.83-64.74) for tricyclic antidepressants. The odds ratios in terms of withdrawals related to adverse events were 1.51 (95% CI 0.33-6.96) for traditional anticonvulsants, 2.98 (95% CI 1.79-5.07) for newer generation anticonvulsants, and 2.32 (95% CI 0.59-9.69) for tricyclic antidepressants.

**Conclusion:** Anticonvulsants and antidepressants are still the most commonly used options to manage diabetic neuropathy. Tricyclic antidepressants and traditional anticonvulsants are better for short-term pain relief than newer anticonvulsants. Evidence of the long-term effects of antidepressants and anticonvulsants is lacking. Further studies are needed on opioids, NMDA antagonists, and ion channel blockers.

C-Peptide

A short peptide released into the circulation when proinsulin is cleaved to insulin

Other Players in Glucose Homeostasis

These hormones act to increase blood glucose levels

- Glucagon
- Epinephrine
- Cortisol
- Growth hormone

C-Peptide

A short peptide released into the circulation when proinsulin is cleaved to insulin
Clinical Features

- Whipple’s triad
  1. serum glucose 45 mg/dL (<2.5 mmol/L) in males and 40 mg/dL (<2.2 mmol/L) in females
  2. neuroglycopenic symptoms
  3. rapid relief provided by administration of glucose
- adrenergic symptoms (typically occur first; caused by autonomic nervous system activity)
  - palpitations, sweating, anxiety, tremor, tachycardia
- neuroglycopenic symptoms (caused by decreased activity of CNS)
  - dizziness, headache, clouding of vision, mental dullness, fatigue, confusion, seizures, coma

Investigations

- electrolytes, creatinine, LFTs, drugs/toxins, cortisol
- if concerned about possible insulinoma:
  - blood work to be drawn when patient is hypoglycemic (e.g. during hospitalized 72 h fast)
  - may need ongoing glucose infusion once BG > 90 mg/dL (5 mmol/L)

Treatment

- for fasting hypoglycemia, must treat underlying cause
- for post-prandial (reactive) hypoglycemia, frequent small feeds
- see Emergency Medicine, EM36
- treatment of hypoglycemic episode in the unconscious patient or patient NPO
  - D50W 50 mL (1 ampule) IV or 1 mg glucagon SC (if no IV available)
  - blood work to be drawn when patient is hypoglycemic (e.g. during hospitalized 72 h fast)
- repeat steps 1-3 until BG > 90 mg/dL
  - 1) Eat 15 g of carbohydrates (CHO)
  - 2) Wait 15 min
  - 3) Retest Blood Glucose (BG)
  - 4) Repeat steps 1-3 until BG > 90 mg/dL
  - 5) Eat next scheduled meal. If next meal is > 1 h away, eat snack including 15 g of CHO and protein.

Metabolic Syndrome

- several definitions, most widely used are National Cholesterol Education Program (NCEP/ATP III, updated by American Heart Association) and International Diabetes Federation (IDF) definitions
- postulated syndrome related to insulin resistance associated with hyperglycemia, hyperinsulinemia, HTN, central obesity, and dyslipidemia
- obesity aggravates extent of insulin resistance
- complications include DM, atherosclerosis, CAD, MI, and stroke
- women with PCOS are at increased risk for developing insulin resistance, hyperlipidemia, and metabolic syndrome
- not to be confused with syndrome X related to angina pectoris with normal coronary arteries (Prinzmetal angina)

Obesity

- see Family Medicine, FM7
Pituitary Gland

Pituitary Hormones

Hypothalamic-pituitary hormonal axes
CRH = corticotropin-releasing hormone; GnRH = gonadotropin-releasing hormone; GHIH = growth hormone-inhibiting hormone; GHRH = growth hormone-releasing hormone; PRH = prolactin-releasing hormone; TRH = thyrotropin-releasing hormone

Hypothalamic Control of Pituitary
- trophic and inhibitory factors control the release of pituitary hormones
- most hormones are primarily under trophic stimulation except prolactin which is primarily under inhibitory control by dopamine, as well as GH and TSH which are inhibited by SS (somatostatin)
- transection of the pituitary stalk (i.e. dissociation of hypothalamus and pituitary) leads to pituitary hypersecretion of prolactin and hyposecretion of all remaining hormones

Anterior Pituitary Hormones
- growth hormone (GH), luteinizing hormone (LH), follicle stimulating hormone (FSH), thyroid stimulating hormone (TSH), adrenocorticotropic hormone (ACTH), and prolactin (PRL)

Posterior Pituitary (Hypothalamic) Hormones
- antidiuretic hormone (ADH) and oxytocin
- peptides synthesized in the supraoptic and paraventricular nuclei of the hypothalamus
- although ADH and oxytocin are produced in the hypothalamus these hormones are stored and released from the posterior pituitary

Table 15. The Physiology and Action of Pituitary Hormones

<table>

</table>

### Growth Hormone

**GH DEFICIENCY**
- cause of short stature in children (see Pediatrics, P27)
- controversial significance in adults; often not clinically apparent, may present as fatigue

**GH EXCESS**
- in children (before epiphyseal fusion) leads to gigantism
- in adults (after epiphyseal fusion) leads to acromegaly

**Etiology**
- GH secreting pituitary adenoma, carcinoid or pancreatic islet tumors secreting ectopic GHRH resulting in excess GH

**Pathophysiology**
- normally GH is a catabolic hormone that acts to increase blood glucose levels
- in growth hormone excess states secretion remains pulsatile but there is loss of hypoglycemic stimulation, glucose suppression, and the nocturnal surge
- proliferation of bone, cartilage, soft tissues, organomegaly
- insulin resistance and IGT

**Clinical Features**
- enlargement of hands and feet, coarsening of facial features, thickening of calvarium, prognathism, thickening of skin, increased sebum production, sweating, acne, sebaceous cysts, fibromata mollusca, acanthosis nigricans, arthralgia, carpal tunnel syndrome, degenerative osteoarthritis, thyromegaly, renal calculi, HTN, cardiomyopathy, obstructive sleep apnea, colonic polyps, and DM

**Signs and Symptoms of Acromegaly:**
- ABCDEF
- Abnormal gait
- Blood pressure raised
- Carpal tunnel syndrome
- Diabetes
- Enlarged organs
- Field defect (visual)
Investigations
- glucose suppression test is the most specific test (75 g of glucose PO suppresses GH levels in healthy individuals but not in patients with acromegaly)
- elevated serum insulin-like growth factor-1 (IGF-1) is usually first line diagnostic test

Treatment
- surgery, octreotide (somatostatin analogue), dopamine agonist (bromocriptine/cabergoline), growth hormone receptor antagonist (pegvisomant), radiation

Prolactin

HYPERPROLACTINEMIA

Etiology
- pregnancy and breastfeeding
- prolactinoma: most common pituitary adenoma (prolactin-secreting tumors may be induced by estrogens and grow during pregnancy)
- pituitary masses with pituitary stalk compression causing reduced dopamine inhibition of prolactin release
- primary hypothyroidism (increased TRH)
- decreased clearance due to chronic renal failure or severe liver disease (prolactin is metabolized by both the kidney and liver)
- medications with anti-dopaminergic properties are a common cause of high prolactin levels: antipsychotics (common), antidepressants, antihypertensives, anti-migraine agents (triptans/ergotamines), bowel motility agents (metoclopramide/domperidone), H2-blockers (ranitidine)
- macroprolactinemia (high molecular weight prolactin also known as big big prolactin)

Clinical Features
- galactorrhea (secretion of breast milk in women and, in rare cases, men), infertility, hypogonadism, amenorrhea, erectile dysfunction

Investigations
- serum PRL, TSH, liver enzyme tests, creatinine
- MRI of the sella turcica

Treatment
- long-acting dopamine agonist: bromocriptine, cabergoline, or quinagolide (Norprolac®)
- surgery ± radiation (rare)
- prolactin-secreting tumors are very slow-growing and sometimes require no treatment
- if medication-induced, consider stopping medication if possible
- in certain cases if microprolactinoma and not planning on becoming pregnant, may consider OCP

Thyroid Stimulating Hormone

- see Thyroid, E20

Adrenocorticotropic Hormone

- see Adrenal Cortex, E29

Luteinizing Hormone and Follicle Stimulating Hormone

- see Gynecology, GY4

HYPOGONADOTROPIC HYPOGONADISM

Clinical Features
- hypogonadism, amenorrhea, erectile dysfunction (see Urology, U30), loss of body hair, fine skin, testicular atrophy, failure of pubertal development

Treatment
- Pergonal® (combined FSH/LH hormone therapy), hCG, or pulsatile GnRH analogue if fertility desired
- symptomatic treatment with estrogen/testosterone

HYPERGONADOTROPIC HYPOGONADISM
- 2nd hypersecretion in gonadal failure (e.g. in menopause)
Antidiuretic Hormone

DIABETES INSIPIDUS

Definition
• disorder of ineffective ADH (decreased production or peripheral resistance) resulting in passage of large volumes of dilute urine

Etiology and Pathophysiology
• central DI: insufficient ADH due to pituitary surgery, tumors, idiopathic/autoimmune, stalk lesion, hydrocephalus, histiocytosis X, trauma, familial central DI
• nephrogenic DI: collecting tubules in kidneys resistant to ADH due to drugs (e.g. lithium), hypercalcemia, hypokalemia, chronic renal disease, hereditary nephrogenic DI
• psychogenic polydipsia and osmotic diuresis must be ruled out

Clinical Features
• passage of large volumes of dilute urine, polydipsia, and dehydration; hypernatremia can develop with inadequate water consumption or secondary to an impaired thirst mechanism

Diagnostic Criteria
• fluid deprivation will differentiate true DI (high urine output persists, urine osmolality < plasma osmolality) from psychogenic DI (psychogenic polydipsia)
• response to exogenous ADH (DDAVP) will distinguish central from nephrogenic DI

Treatment
• DDAVP/vasopressin for central DI
• chlorpropamide, clofibrate, thiazides, NSAIDs, or carbamazepine as second line or for partial DI
• nephrogenic DI treated with solute restriction NSAIDs and thiazide diuretics; DDAVP (if partial)

SYNDROME OF INAPPROPRIATE ADH SECRETION

Diagnostic Criteria
• hyponatremia with corresponding plasma hypo-osmolality, urine sodium concentration above 40 mEq/L, urine less than maximally diluted (>100 mOsm/kg), euvolemia (edema absent), and absence of adrenal, renal, or thyroid insufficiency

Etiology and Pathophysiology
• stress (pain, nausea, post-surgical)
• malignancy (lung, pancreas, lymphoma)
• CNS disease (inflammatory, hemorrhage, tumor, Guillain-Barré syndrome)
• respiratory disease (TB, pneumonia, empyema)
• drugs (SSRIs, vincristine, chlorpropamide, cyclophosphamide, carbamazepine, nicotine, morphine, DDAVP, oxytocin)

Treatment
• treat underlying cause, fluid restriction (800-1000 mL/day), vasopressin receptor antagonists (e.g. tolvaptan, conivaptan), and demeclocycline (antibiotic with anti-ADH properties, rarely-used) fludrocortisone, furosemide

Pituitary Pathology

PITUITARY ADENOMA (see Neurosurgery, NS13)

Clinical Features
• local mass effects
  • visual field defects (bitemporal hemianopsia due to compression of the optic chiasm), diplopia (due to oculomotor nerve palsies), headaches; increased ICP is rare
  • hypofunction
  • hypopituitarism
  • hyperfunction
  • PRL (galactorrhea), GH (acromegaly in adults, gigantism in children), ACTH (Cushing’s disease = Cushing’s syndrome caused by a pituitary tumor)
  • tumors secreting LH, FSH, and TSH are rare

Investigations
• radiological evaluation (MRI is imaging procedure of choice)
• formal visual field testing
• hypothalamic-pituitary hormonal function
HYPOPITUITARISM

Etiology (the eight Is)
- Invasive
  - pituitary tumors, craniopharyngioma, cysts (Rathke's cleft, arachnoid, or dermoid), metastases
- Infarction/hemorrhage
  - Sheehan's syndrome (pituitary infarction due to excessive post-partum blood loss and hypovolemic shock)
  - pituitary apoplexy (acute hemorrhage/infarction of a pituitary tumor; presents with sudden loss of pituitary hormones, severe headache, and altered level of consciousness; can be fatal if not recognized and treated early)
- Infiltrative/inflammatory
  - sarcoidosis, hemochromatosis, histiocytosis
- Infectious
  - syphilis, TB, fungal (histoplasmosis), parasitic (toxoplasmosis)
- Injury
  - severe head trauma
- Immunologic
  - autoimmune destruction
- Iatrogenic
  - following surgery or radiation
- Idiopathic
  - familial forms, congenital midline defects

Investigations
- triple bolus test
  - stimulates release of all anterior pituitary hormones in normal individuals
  - rapid sequence of IV infusion of insulin, GnRH, and TRH
    - insulin (usual dose 0.1 unit/kg of human regular insulin) → hypoglycemia → increased GH and ACTH
    - GnRH (100 µg IV push) → increased LH and FSH
    - TRH (200 µg IV push over 120 s) → increased TSH and PRL (no longer available)

Thyroid

Thyroid Hormones

Synthetic Function of Thyroid Gland
- the synthesis of thyroid hormones $T_3$ (thyroxine) and $T_4$ (triiodothyronine) by the thyroid gland involves trapping and oxidation of iodide, iodination of thyroglobulin, and release of $T_3$ and $T_4$
• free T<sub>3</sub> (0.03%) and free T<sub>4</sub> (0.3%) represent the hormonally active fraction of thyroid hormones
  ▪ the remaining fraction is bound to thyroxine binding globulin (TBG) and albumin and is biologically inactive
• T<sub>3</sub> is more biologically active (3-8x more potent), but T<sub>4</sub> has a longer half-life
• 85% of T<sub>4</sub> is converted to T<sub>3</sub> or reverse T<sub>3</sub> (RT3) in the periphery by deiodinases
• RT3 is metabolically inactive but produced in times of stress to decrease metabolic activity
• most of the plasma T<sub>3</sub> pool is derived from the peripheral conversion of T<sub>4</sub>
• calcitonin, a peptide hormone, is also produced in the thyroid, by the parafollicular cells or C cells
  ▪ it functions by inhibiting osteoclast activity and increasing renal calcium excretion

Role of Thyroid Hormones
• thyroid hormones act primarily through modifying gene transcription by binding to nuclear receptors
• action of these hormones is diffuse, effecting nearly every organ system
• they produce an increase in basal metabolic rate including: increased Na<sup>+</sup>/K<sup>+</sup> ATPase activity, increased O<sub>2</sub> consumption, increased respiration, heat generation, and increased cardiovascular activity
• also play crucial role during fetal life in both neurological and somatic development

Regulation of Thyroid Function
• extrathyroid
  ▪ stimulation of thyroid by TSH, epinephrine, prostaglandins (cAMP stimulators)
  ▪ T<sub>3</sub> negatively feeds back on anterior pituitary to inhibit TSH and on hypothalamus to inhibit TRH
• intrathyroid (autoregulation)
  ▪ synthesis (Wolff-Chaikoff effect, Jod-Basedow effect)
  ▪ there is varying thyroid sensitivity to TSH in response to iodide availability
  ▪ increased ratio of T<sub>3</sub> to T<sub>4</sub> in iodide deficiency
  ▪ increased activity of peripheral 5' deiodinase in hypothyroidism increases T<sub>3</sub> production despite low T<sub>4</sub> levels

Tests of Thyroid Function and Structure

TSH
• sensitive TSH (sTSH) is the best test for assessing thyroid function
• hyperthyroidism
  ▪ primary: TSH is low because of negative feedback from increased levels of circulating T<sub>3</sub> and T<sub>4</sub>
  ▪ secondary: increased TSH results in increased T<sub>3</sub> and T<sub>4</sub>
• hypothyroidism
  ▪ primary: increased TSH (most sensitive test) because of less negative feedback from T<sub>3</sub> and T<sub>4</sub>
  ▪ secondary: TSH is low or normal with variable response to TRH depending on the site of the lesion (pituitary or hypothalamic)

Free T<sub>3</sub> and Free T<sub>4</sub>
• standard assessment of thyroid function measures TSH and if necessary free T<sub>3</sub>. free T<sub>4</sub> should be measured if TSH is suppressed and free T<sub>4</sub> is normal to rule out T<sub>3</sub> toxicity

Thyroid Autoantibodies
• anti-thyroglobulin antibodies (TgAb), anti-thyroid peroxidase antibodies, anti-TSH-receptor inhibiting antibodies
  ▪ increased in Hashimoto’s disease; normal variant in 10-20% of individuals
• thyroid stimulating immunoglobulin (TSI)/TSH receptor stimulating antibodies

Plasma Calcitonin
• used to monitor for residual thyroid tissue post-thyroidectomy, e.g. tumor marker for thyroid cancer recurrence
• normal or elevated levels may suggest persistent, recurrent, or metastatic disease

Serum Calcitonin
• not routinely done to investigate thyroid nodules
• ordered if suspicion of medullary thyroid carcinoma or family history of MEN IIa or IIb syndromes
• used to monitor for residual or recurrent medullary thyroid cancer

Thyroid Imaging/Scans
• normal gland size 15-20 g (estimated by palpation)
• thyroid U/S
  ▪ to measure size of gland, solid vs. cystic nodule, facilitate fine needle aspirate biopsy (FNAB)
• radioisotope thyroid scan (Technetium-99)
  ▪ test of structure: order if there is a thyroid nodule and patient is hyperthyroid with low TSH
  ▪ differentiates between hot (functioning → excess thyroid hormone production) and cold (non-functioning) nodules
    ▪ hot nodule → very low chance malignancy; treat hyperthyroidism
    ▪ cold nodule → ~5% chance malignancy; further workup required (U/S and FNAB)

### Patterns of Hormone Levels

<table>
<thead>
<tr>
<th></th>
<th>TSH</th>
<th>T&lt;sub&gt;3&lt;/sub&gt;</th>
<th>T&lt;sub&gt;4&lt;/sub&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>1° Hyper</td>
<td>†</td>
<td>†</td>
<td>†</td>

</tbody>
</table>

### Weight Reference

- **LR+**: 0.20-0.30
- **LR-**: 0.80-0.90

<table>
<thead>
<tr>
<th>Weight (g)</th>
<th>Reference</th>
<th>LR+ (95% CI)</th>
<th>LR- (95% CI)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-20 g</td>
<td>normal</td>
<td>0.15 (0.10-0.21)</td>
<td>1.0 (0.1-10)</td>
</tr>
<tr>
<td>20-40 g</td>
<td>1x</td>
<td>1.9 (1.1-3.5)</td>
<td>0.9 (0.1-10)</td>
</tr>
<tr>
<td>&gt;40 g</td>
<td>2x</td>
<td>25.0 (2.6-175)</td>
<td>0.15 (0.1-1.0)</td>
</tr>
</tbody>
</table>

Alternatively, defining a goiter as mass larger than 40 g >2x 25.0 (2.6-175) and <40 g <2x 25.0 (0.1-2.6) has a LR+ of 3.0 (95% CI 2.5-3.5) and LR- of 0.30 (95% CI 0.24-0.37) in children, and an LR+ of 4.7 (95% CI 3.6-6.0) and LR- of 0.08 (95% CI 0.02-0.27) for the presence of a goiter.

Conclusions: Use of weight of thyroid tissue is an appropriate method of diagnosing a goiter, while comparing the size of thyroid mass to the distal phalanx of the thumb has been shown to have an LR+ of 3.6-6.0 (2.6-175) and LR- of 0.08 (0.02-0.27) for the presence of a goiter.

### Thyroid Assessment
- Serum thyroid hormones (TSH, T<sub>3</sub>, T<sub>4</sub>)
- Antibodies
- Thyroglobulin (to monitor thyroid cancer)
- Thyroid U/S
- Nuclear uptake and scan (for hyperthyroidism)
- Biopsy (FNA)
radioactive iodine uptake (RAIU)
- test of function: order if patient is thyrotoxic
- RAIU measures the turnover of iodine by thyroid gland in vivo
- if ↑ uptake (i.e. incorporated) → gland is overactive (hyperthyroid)
- if ↓ uptake (i.e. not incorporated) → gland is leaking thyroid hormone (e.g. thyroiditis), exogenous thyroid hormone use, or excess iodine intake (e.g. amiodarone or contrast dye, which has high iodine content)

• see Figure 8, Approach to the Evaluation of a Thyroid Nodule, E29 for further information regarding the utility of these scans

Thyroid Biopsy
- fine needle aspiration (FNA) for cytology
  - differentiates between benign and malignant disease
  - best done under U/S guidance
  - accuracy decreased if nodule is greater than 50% cystic, or if nodule located posteriorly in the gland

Treatment

- thionamides: PTU or MMI; MMI recommended (except in first trimester pregnancy)
- β-blockers for symptom control
- radioactive iodine thyroid ablation for Graves' disease
- surgery in the form of hemi, sub-total, or complete thyroidectomy

Graves’ Disease

Definition

- an autoimmune disorder characterized by autoantibodies to the TSH receptor that leads to hyperthyroidism

Epidemiology

- most common cause of thyrotoxicosis
- occurs at any age with peak in 3rd and 4th decade
- F>M = 7:1, 1.5-2% of U.S. women
- familial predisposition: 15% of patients have a close family member with Graves' disease and 50% have family members with positive circulating antibodies
- association with HLA B8 and DR3
- may be associated with other inherited autoimmune disorders (e.g. pernicious anemia, Hashimoto's disease)

Etiology and Pathophysiology

- autoimmune disorder due to a defect in T-suppressor cells
- B lymphocytes produce TSI that binds and stimulates the TSH receptor and stimulates the thyroid gland
- immune response can be triggered by postpartum state, iodine excess, lithium therapy, viral or bacterial infections, glucocorticoid depletion (an acute phase response) of TSH, resulting in increased tissue volume due to inflammation and accumulation of glycosaminoglycans, stimulated by TSI, that increase osmotic pressure within the orbitis leads to fluid accumulation and displacement of the eye ball forward
- dermopathy may be related to cutaneous glycosaminoglycan deposition

Clinical Features

- signs and symptoms of thyrotoxicosis
- diffuse thyroid goiter ± thyroid bruit secondary to increased blood flow through the gland
- ophthalmopathy: proptosis, dioplia, conjunctival injection, corneal abrasions, periorbital puffiness, lid lag, decreased visual acuity if Graves’ (plus signs of hyperthyroidism: lid retraction, characteristic stare)
• risk of relapse is 37%, 21%, 6% in thionamides, radioiodine ablation, and surgery groups, respectively

Investigations
• low TSH
• increased free T4 (and/or increased T3)
• positive for TSI
• increased radioactive iodine (I-131) uptake
• homogeneous uptake on thyroid scan (only do this test in the presence of nodule)

Treatment
• thionamides
  - propylthiouracil (PTU) or methimazole (MMI)
  - inhibit thyroid hormone synthesis by inhibiting peroxidase-catalyzed reactions, thereby inhibiting organization of iodide, blocking the coupling of iodotyrosines
  - PTU also inhibits peripheral deiodination of T4 to T3
  - continue treatment until remission occurs (20-40% of patients achieve spontaneous remission at 6-18 mo of treatment)
  - small goiter and recent onset are good indicators for long-term remission with medical therapy
  - major side effects: hepatitis, agranulocytosis, and fever/arthralgias
  - minor side effects: rash
  - iodinated contrast agents: sodium ipodate and iopanoic acid can inhibit conversion of T4 to T3 and are especially effective in combination with MMI
  - MMI preferred vs. PTU due to longer duration of action (once daily for most), more rapid efficacy, and lower incidence of side effects
  - MMI contraindicated in pregnancy (teratogenic), use PTU
• β-blockers
• thyroid ablation with radioactive 131I if PTU or MMI trial does not produce disease remission
  - high incidence of hypothyroidism after 131I requiring lifelong thyroid hormone replacement
  - contraindicated in pregnancy
  - may worsen ophthalmopathy
• subtotal or total thyroidectomy (indicated rarely for large goiters, suspicious nodule for CA, if patient is intolerant to thionamides and refusing RAI ablation)
• ophthalmopathy/orbitopathy
  - smoking cessation is most important
  - prevent drying
  - high dose prednisone in severe cases
  - orbital radiation, surgical decompression

Prognosis
• course remission and exacerbation unless gland is destroyed by radioactive iodine or surgery
• lifetime follow-up needed
• risk of relapse is 37%, 21%, 6% in thionamides, radioiodine ablation, and surgery groups, respectively

Subacute Thyroiditis (Thyrotoxic Phase)

Definition
• acute inflammatory disorder of the thyroid gland characterized by an initial thyrotoxic state followed by hypothyroidism eventually followed by euthyroidism in most cases
• two subtypes: painful and painless

Etiology and Pathophysiology
• acute inflammation of the thyroid gland characterized by giant cells and lymphocytes
• disruption of thyroid follicles by inflammatory process results in the release of stored hormone rather than excessive production of new thyroid hormone
• painful = viral (usually preceded by URTI), De Quervain’s (granulomatous thyroiditis)
• painless = postpartum, auto-immune, lymphocytic
  - occurs in 5-10% of postpartum mothers and is symptomatic in 1/3 of patients

Clinical Features
• two forms
  - painful (“De Quervain’s”) thyroid, ears, jaw, and occiput
  - painless (“Silent”)
• fever and malaise may be present, especially in De Quervain’s
• postpartum: thyrotoxicosis 2-3 mo postpartum with a subsequent hypothyroid phase at 4-8 mo postpartum
• may be mistakenly diagnosed as postpartum depression

Laboratory Investigations
• initial elevated free T₄, T₃, low TSH, RAIU markedly reduced
• marked elevation of ESR in painful variety only
• as disease progresses values consistent with hypothyroidism may appear

Treatment
• painful – high dose NSAIDs, prednisone may be required for severe pain, fever, or malaise
• iodinated contrast agents (e.g. iopanoic acid, ipodate) to inhibit peripheral conversion of T₄ to T₃
• β-adrenergic blockade is usually effective in reversing most of the hypermetabolic and cardiac symptoms in both subtypes
• if symptomatically hypothyroid, may treat short-term with thyroxine

Prognosis
• full recovery in most cases, but permanent hypothyroidism in 10% of painless thyroiditis
• postpartum: most resolve spontaneously without need for supplementation, however may recur with subsequent pregnancies

Toxic Adenoma/Toxic Multinodular Goiter

Etiology and Pathophysiology
• autonomous thyroid hormone production from a functioning adenoma that is hypersecreting T₃ and T₄
• may be singular (toxic adenoma) or multiple (toxic multinodular goiter [Plummer’s disease])

Clinical Features
• goiter with adenomatous changes
• tachycardia, heart failure, arrhythmia, weight loss, nervousness, weakness, tremor, and sweats
• seen most frequently in elderly people, often with presentation of atrial fibrillation

Investigations
• low TSH, high T₃ and T₄
• thyroid scan with increased uptake in nodule(s) and suppression of the remainder of the gland

Treatment
• initiate therapy with PTU or MMI to attain euthyroid state
• use high dose radioactive iodine (I-131) to ablate hyperfunctioning nodules
• β-blockers often necessary for symptomatic treatment prior to definitive therapy
• surgical excision may also be used as 1st line treatment

Thyrotoxic Crisis/Thyroid Storm

Definition
• acute exacerbation of all of the symptoms of thyrotoxicosis presenting in a life-threatening state secondary to uncontrolled hyperthyroidism – medical emergency
• rare, but serious with mortality rate between 20-30%

Etiology and Pathophysiology
• often precipitated by infection, trauma, or surgery in a hyperthyroid patient

Differential Diagnosis
• sepsis, pheochromocytoma, malignant hyperthermia, drug overdose, neuroleptic malignant syndrome

Clinical Features
• hyperthyroidism
• extreme hyperthermia, tachycardia, vomiting, diarrhea, vascular collapse, hepatic failure with jaundice, and confusion
• tachyarrhythmia, CHF, shock
• mental status changes ranging from delirium to coma
Laboratory Investigations
- increased free T₃ and T₄, undetectable TSH
- ± anemia, leukocytosis, hyperglycemia, hypercalcemia, elevated LFTs

General Measures
- fluids, electrolytes, and vasopressor agents should be used as indicated
- a cooling blanket and acetaminophen can be used to treat the pyrexia
- propranolol or similar agents for beta-adrenergic blockade is used, which additionally causes decreased peripheral conversion of T₄ → T₃
  - use with caution in CHF patients as it may worsen condition

Specific Measures
- PTU is the anti-thyroid drug of choice and is used in high doses
- Give iodide, which acutely inhibits the release of thyroid hormone, 1 h after the first dose of PTU is given
  - Sodium iodide 1 gm IV drip over 12h q12h
  - Lugol's solution 2-3 drops q8h
  - Potassium iodide (SSKI) 5 drops q8h
- dexamethasone 2-4 mg IV q6h for the first 24-48 h lowers body temperature and inhibits peripheral conversion of T₄ → T₃

Prognosis
- probably <20% mortality rate if rapidly recognized and treated

Hypothyroidism

Definition
- clinical syndrome caused by cellular responses to insufficient thyroid hormone production

Epidemiology
- 2-3% of general population
- F:M = 10:1
- 10-20% of women over age 50 have subclinical hypothyroidism (normal T₄, TSH mildly elevated)
- iodine deficiency most common cause worldwide, but not in North America

Etiology and Pathophysiology
- primary hypothyroidism (90%)
  - inadequate thyroid hormone production secondary to intrinsic thyroid defect
  - iatrogenic: post-ablative (¹³¹I or surgical thyroidectomy)
  - autoimmune: Hashimoto's thyroiditis, chronic thyroiditis, idiopathic, burnt out Graves'
  - hypothyroid phase of subacute thyroiditis
  - drugs: goitrogens (iodine), PTU, MMI, lithium
  - infiltrative disease (progressive systemic sclerosis, amyloid)
  - iodine deficiency
  - congenital (1/4,000 births)
  - neoplasia
- secondary hypothyroidism: pituitary hypothyroidism
- insufficiency of pituitary TSH
- tertiary hypothyroidism: hypothalamic hypothyroidism
- decreased TRH from hypothalamus (rare)
- peripheral tissue resistance to thyroid hormone (Refetoff syndrome)

Thyroid Hormone Replacement for Subclinical Hypothyroidism

Purpose: To assess the effects of thyroid hormone replacement for subclinical hypothyroidism.

Study Selection: RCTs comparing thyroid hormone replacement with placebo in adults with subclinical hypothyroidism. Minimum duration of follow-up was 1 mo.

Results: No trial assessed (cardiovascular) mortality or morbidity. Seven studies evaluated symptoms, mood, and quality of life with no statistically significant improvement. One study showed a statistically significant improvement in cognitive function. Six studies assessed serum lipids, there was a trend for reduction in some parameters following levothyroxine replacement. Some echocardiographic parameters improved after levothyroxine replacement therapy, like myocardial relaxation. Only four studies reported adverse events with no statistically significant differences between groups.

Conclusions: In current RCTs, levothyroxine replacement therapy for subclinical hypothyroidism did not result in improved survival or decreased cardiovascular morbidity. Data on health-related quality of life and symptoms did not demonstrate significant differences between intervention groups. Some evidence indicates that levothyroxine replacement improves some parameters of lipid profiles and left ventricular function.

Signs and Symptoms of Hypothyroidism

HIS FIRM CAP
- Hypoventilation
- Intolerance to cold
- Slow HR
- Fatigue
- Impotence
- Renal impairment
- Menorrhagia/amenorrhea
- Constipation
- Anemia
- Paresthesia
Clinical Features

Table 20. Clinical Features of Hypothyroidism

<table>
<thead>
<tr>
<th>General</th>
<th>Fatigue, cold intolerance, slowing of mental and physical performance, hoarseness, macroglossia</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVS</td>
<td>Pericardial effusion, bradycardia, hypotension, worsening CHF + angina, hypercholesterolemia, hyperhomocysteinemia, myxedema heart</td>
</tr>
<tr>
<td>Respiratory</td>
<td>Decreased exercise capacity, hypoventilation secondary to weak muscles, decreased pulmonary responses to hypoxia, sleep apnea due to macroglossia</td>
</tr>
<tr>
<td>GI</td>
<td>Weight gain despite poor appetite, constipation</td>

</tr>
</tbody>
</table>

Treatment

- L-thyroxine (dose range: 0.05-0.2 mg PO OD ~1.6 μg/kg/d)
- elderly patients and those with CAD: start at 0.025 mg daily and increase gradually every 6 wk (start low, go slow)
- after initiating L-thyroxine, TSH needs to be evaluated in 6 wk; dose is adjusted until TSH returns to normal reference range
- once maintenance dose achieved, follow-up TSH with patient annually
- secondary/tertiary hypothyroidism
  - monitor via measurement of free T₄ (TSH is unreliable in this setting)

CONGENITAL HYPOTHYROIDISM

- see Pediatrics, P29

Hashimoto’s Thyroiditis

- most common form of primary hypothyroidism in North America
- chronic autoimmune thyroiditis characterized by both cellular and humoral factors in the destruction of thyroid tissue
- two major forms: goitrous and atrophic; both forms share same pathophysiology but differ in the extent of lymphocytic infiltration, fibrosis, and thyroid follicular cell hyperplasia
- goitrous variant usually presents with a rubbery goiter and euthyroidism, then hypothyroidism becomes evident
  - associated with fibrosis
- atrophic variant patients are hypothyroid from the start
  - associated with thyroid lymphoma

Etiology and Pathophysiology

- defect in clone of T-suppressors leads to cell-mediated destruction of thyroid follicles
- B lymphocytes produce antibodies against thyroid components including thyroglobulin, thyroid peroxidase, TSH receptor, Na⁺/I symporter

Risk Factors

- female gender
- genetic susceptibility: increased frequency in patients with Down’s syndrome, Turner’s syndrome, certain HLA alleles, cytotoxic T-lymphocyte-associated protein 4 (CTLA-4)
- family Hx or personal Hx of other autoimmune diseases
- cigarette smoking
- high iodine intake
- stress and infection

Investigations

- high TSH, low T₄ (not necessary to measure T₃ as it will be low as well)
- presence of thyroid peroxidase and thyroglobulin antibodies in serum

Treatment

- if hypothyroid, replace with L-thyroxine (analog of T₄)
Myxedema Coma

Definition
- severe hypothyroidism complicated by trauma, sepsis, cold exposure, MI, inadvertent administration of hypnotics or narcotics, and other stressful events – medical emergency!
- rare, high level of mortality when it occurs (up to 60%, despite therapy)

Clinical Features
- hallmark symptoms of decreased mental status and hypothermia; hyponatremia, hypotension, hypoglycemia, bradycardia, hypoventilation, and generalized edema often present

Investigations
- decreased T₄, increased TSH, decreased glucose
- check ACTH and cortisol for evidence of adrenal insufficiency

Treatment
- aggressive treatment required
- ABCs: ICU admission
- corticosteroids (for risk of concomitant adrenal insufficiency): hydrocortisone 100 mg q8h
- L-thyroxine 0.2-0.5 mg IV loading dose, then 0.1 mg IV OD until oral therapy tolerated; also consider T₃ therapy
- supportive measures: mechanical ventilation, fluids, vasopressor drugs, passive rewarming, IV dextrose
- monitor for arrhythmia

Sick Euthyroid Syndrome

Definition
- changes in circulating thyroid hormones amongst patients with serious illness, trauma, or stress
- not due to intrinsic thyroid or pituitary disease
- initially low free T₃ may be followed by low TSH and if severe illness low free T₄
- with recovery of illness, TSH may overshoot and become transiently high

Pathophysiology
- abnormalities in SES include alterations in
  - peripheral transport and metabolism of thyroid hormone
  - regulation of TSH secretion
  - thyroid function itself
  - peripheral conversion of T₄ to T₃

Labs
- initially decreased free T₃ followed by decreased TSH and finally decreased free T₄

Treatment
- treat the underlying disease; thyroid hormone replacement worsens outcomes
- thyroid function tests normalize once patient is well (initially with a transient increase in TSH)

Non-Toxic Goiter

Definition
- generalized enlargement of the thyroid gland in a euthyroid individual that does not result from inflammatory or neoplastic processes

Pathophysiology
- the appearance of a goiter is more likely during adolescence, pregnancy, and lactation because of increased thyroid hormone requirements
  - early stages: goiter is usually diffuse
  - later stages: multinodular non-toxic goiter with nodule, cyst formation and areas of ischemia, hemorrhage, and fibrosis

Etiology
- iodine deficiency or excess
- goitrogens: brassica vegetables (e.g. turnip, cassava)
- drugs: iodine, lithium, para-aminosalicylic acid
- any disorder of hormone synthesis with compensatory growth
- peripheral resistance to thyroid hormone
Treatment
• remove goitrogens
• radiiodine therapy (need very high doses, low iodine uptake, used as last resort)
• suppression with L-thyroxine (rarely done)
• surgery may be necessary for severe compressive symptoms

Complications
• compression of neck structures causing stridor, dysphagia, pain, and hoarseness
• multinodular goiter may become autonomous leading to toxic multinodular goiter and hyperthyroidism

Thyroid Nodules
Definition
• clearly defined discrete mass, separated from the thyroid parenchyma
• palpable nodules are found in approximately 5% of the population
• M:F = 1:4

Etiology
• benign tumors (e.g. colloid nodule, follicular adenoma)
• thyroid malignancy
• hyperplastic area in a multinodular goiter
• cyst: true thyroid cyst, area of cystic degeneration in a multinodular goiter

Investigations

Figure 8. Approach to the evaluation of a thyroid nodule
Adapted from Dr. J Goguen, University of Toronto, MMMD 2013

Thyroid Malignancies
• see Otolaryngology, OT38

Adrenal Cortex

Adrenocorticotropic Hormone
• a polypeptide (cleaved from prohormone POMC), secreted in a pulsatile fashion from the anterior pituitary with diurnal variability (peak: 0200-0400; trough: 1800-2400)
• secretion regulated by corticotropin-releasing hormone (CRH) and arginine vasopressin (AVP)
• stimulates growth of adrenal cortex and release of glucocorticoids, androgens and, to a limited extent, mineralocorticoids
• some melanocyte stimulating activity

Adrenocortical Hormones
Aldosterone
• a mineralocorticoid which regulates extracellular fluid (ECF) volume through Na⁺ (and Cl⁻) retention and K⁺ (and H⁺) excretion (stimulates distal tubule Na⁺/K⁺ ATPase)
• regulated by the renin-angiotensin-aldosterone system (Figure 11)
• negative feedback to juxtaglomerular apparatus (JGA) by long loop (aldosterone → volume expansion) and short loop (angiotensin II → peripheral vasoconstriction)
Cortisol
- a glucocorticoid, regulated by the HPA axis
- involved in regulation of metabolism; counteracts the effects of insulin
- support blood pressure, vasomotor tone
- also involved in regulation of behavior and immunosuppression

</tbody>
</table>

Androgens
- sex steroids regulated by ACTH; primarily responsible for adrenarche (growth of axillary and pubic hair)
- principal adrenal androgens are dehydroepiandrosterone (DHEA), androstenedione, and 11-hydroxyandrostenedione
- proportion of total androgens (adrenal to gonadal) increases in old age
Adrenocortical Functional Workup

**STIMULATION TEST**
- **purpose:** diagnosis of hormone deficiencies
- **method:** measure target hormone after stimulation with tropic (pituitary) hormone

1. **Tests of Glucocorticoid Reserve**
   - **Cosyntropin (ACTH analogue) Stimulation Test**
     - give 1 µg or 250 µg cosyntropin IV, then measure plasma cortisol levels at time 0, 30, and 60 min
     - physiologic response: stimulated plasma cortisol of >18 µg/dL (500 nmol/L)
     - inappropriate response: inability to stimulate increased plasma cortisol
   - insulin tolerance test used to diagnose secondary or tertiary hypoadrenalism (see Pituitary Gland, E16)

2. **SUPPRESSION TESTS**
   - **purpose:** diagnosis of hormone hypersecretion
   - **method:** measure target hormone after suppression of its tropic (pituitary) hormone

1. **Tests of Pituitary-Adrenal Suppressibility**
   - **Dexamethasone (DXM) Suppression Test**
     - **principle:** DXM suppresses pituitary ACTH → plasma cortisol should be lowered if HPA axis is normal
     - **Screening Test:** Overnight DXM Suppression Test
       - oral administration of 1 mg DXM at midnight → measure plasma cortisol levels the following day at 8 am
       - physiologic response: plasma cortisol <1.8 µg/dL (50 nmol/L), with 1.8-5.0 µg/dL (50-140 nmol/L) being a “grey zone” (cannot be certain if normal or not)
       - inappropriate response: failure to suppress plasma cortisol
       - <20% false positive results due to obesity, depression, alcohol, other medications
     - **Confirmatory Test:** Other testing is used to confirm the diagnosis, such as:
       - midnight salivary cortisol (if available), shows lack of diurnal variation
       - inappropriate response: remains high (normally will be low at midnight)

2. **Tests of Mineralocorticoid Suppressibility**
   - **principle:** expansion of extracellular fluid volume (ECFV) → plasma aldosterone should be lowered if HPA axis were normal
   - **ECFV Expansion with Normal Saline (NS)**
     - IV infusion of 500 mL/h of NS for 4 h → then measure plasma aldosterone levels
     - plasma aldosterone >10 ng/dL (>277 pmol/L) is consistent with primary hyperaldosteronism, <5 ng/dL (<140 pmol/L) is normal
     - inappropriate response: failure to suppress plasma aldosterone
Mineralocorticoid Excess Syndromes

**Definition**
- primary hyperaldosteronism (PH): excess aldosterone production (intra-adrenal cause)
- secondary hyperaldosteronism (SH): aldosterone production in response to excess RAAS (extra-adrenal cause)

**Etiology**
- primary hyperaldosteronism
  - aldosterone-producing adrenal adenoma (Conn’s syndrome)
  - bilateral or idiopathic adrenal hyperplasia
  - glucocorticoid-remediable aldosteronism
  - aldosterone-producing adrenocortical carcinoma
  - unilateral adrenal hyperplasia
- secondary hyperaldosteronism

**Clinical Features**
- HTN
- hypokalemia (may have mild hypernatremia), metabolic alkalosis
- normal K+, low Na+ in SH (low effective circulating volume leads to ↑ ADH release) → edema
- increased cardiovascular risk: LV hypertrophy, atrial fibrillation, stroke, MI
- fatigue, weakness, paresthesia, headache; severe cases with tetany, intermittent paralysis

**Diagnosis**
- investigate plasma aldosterone to renin ratio in patients with HTN and hypokalemia
- confirmatory testing for PH: aldosterone suppression test (demonstrate inappropriate aldosterone secretion with ECFV expansion)
- imaging: CT adrenal glands

**Table 22. Diagnostic Tests in Hyperaldosteronism**

<td>↑ plasma aldosterone</td>
<td></td>
</tr>
</tbody>
</table>

**Treatment**
- inhibit action of aldosterone: spironolactone, eplerenone, triamterene, amiloride (act on sodium channels)
- surgical excision of adrenal adenoma
- secondary hyperaldosteronism: treat underlying cause
Cushing’s Syndrome

Definition
• results from chronic glucocorticoid excess (endogenous or exogenous sources)

Etiology
• ACTH-dependent (85%) – bilateral adrenal hyperplasia and hypersecretion due to:
  ▪ ACTH-secreting pituitary adenoma (Cushing’s disease; 80% of ACTH-dependent)
  ▪ ectopic ACTH-secreting tumor (e.g. small cell lung carcinoma, bronchial, carcinoid, pancreatic islet cell, pheochromocytoma, or medullary thyroid tumors)
• ACTH-independent (15%)
  ▪ long-term use of exogenous glucocorticoids
  ▪ primary adrenocortical tumors: adenoma and carcinoma (uncommon)
  ▪ bilateral adrenal nodular hyperplasia

Clinical Features
• symptoms: weakness, insomnia, mood disorders, impaired cognition, easy bruising, oligo-/amenorrhea, hirsutism, and acne (ACTH dependent)
• signs: central obesity, round face, supraclavicular and dorsal fat pads, facial plethora, proximal muscle wasting, purple abdominal striae, skin atrophy, acanthosis nigricans, HTN, hyperglycemia, osteoporosis, pathologic fractures, hyperpigmentation, hyperandrogenism if ACTH-dependent

Figure 14. Hypercortisolism: algorithm for diagnosis

Treatment
• adrenal
  ▪ adenoma: unilateral adrenalectomy (curative)
  ▪ carcinoma: adjunctive chemotherapy often not useful (frequent metastases, poor prognosis)
  ▪ medical treatment: mitotane, ketoconazole to reduce cortisol
• pituitary
  ▪ trans-sphenoidal resection, with glucocorticoid supplement post-operatively
  ▪ ectopic ACTH tumor (paraneoplastic syndrome): usually bronchogenic cancer (poor prognosis)
    ▪ surgical resection, if possible; chemotherapy/radiation for primary tumor
    ▪ agents blocking adrenal steroid synthesis: metyrapone or ketoconazole

Congenital Adrenal Hyperplasia

• see Pediatrics, P30
Hyperandrogenism

Definition

• state of having excessive secretion of androgens (DHEA, DHEA sulfate, testosterone)

Etiology and Pathophysiology

Table 23. Etiology of Hyperandrogenism

Clinical Features

Females

• hirsutism
  ▪ male pattern growth of androgen-dependent terminal body hair in women: back, chest, upper abdomen, face, linea alba
  ▪ Ferriman-Gallwey scoring system is used to quantify severity of hirsutism
• virilization
  ▪ masculinization: hirsutism, temporal balding, clitoral enlargement, deepening of voice, acne
  ▪ increase in musculature
• defeminization
  ▪ loss of female secondary sex characteristics (i.e. amenorrhea, ↓ breast size, infertility)

Males

• minimal effects on hair, muscle mass, etc.
• inhibition of gonadotropin secretion may cause reduction in: testicular size, testicular testosterone production, and spermatogenesis

Investigations

• testosterone, DHEA-S as a measure of adrenal androgen production
• LH/FSH (commonly in PCOS >2.5)
• 17-OH progesterone, elevated in CAH due to 21-OH deficiency
• for virilization: CT/MRI of adrenals and ovaries (identify tumors)
• if PCOS, check blood glucose, lipids, 75 g OGTT

Treatment

• discontinue causative medications
  ▪ antiandrogens, e.g. spironolactone
• oral contraceptives (e.g. cyproterone acetate – blocks androgen receptor; found in Diane 35°)
• surgical resection of tumor
• low dose glucocorticoid ± mineralocorticoid if CAH suspected
• treat specific causative disorders, e.g. tumors, Cushing’s, etc.
• cosmetic therapy (laser, electrolysis)

Conditions that do NOT Represent True Hirsutism

• Androgen-independent hair (e.g. lanugo hair)
• Drug-induced hypertrichosis (e.g. phenytoin, diazoxide, cyclosporine, minoxidil)
• Topical steroid use
Adrenocortical Insufficiency

Definition
- a state of inadequate cortisol and aldosterone production by the adrenal glands

Etiology

PRIMARY (ADDISON’S DISEASE)

<table>
<thead>
<tr>
<th>Autoimmune (70-90%)</th>
<th>Isolated adrenal insufficiency</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Polyglandular autoimmune syndrome type I and II</td>

</tbody>
</table>

Infection
- TB (7-20%) (most common in developing world)
- Fungal: histoplasmosis, paracoccidioidomycosis
- HIV, CMV
- Syphilis
- African trypanosomiasis

Infiltrative
- Metastatic cancer (lung > stomach > esophagus > colon > breast; lymphoma)
- Sarcoidosis, amyloidosis, hemochromatosis

Vascular
- Bilateral adrenal hemorrhage
- Sepsis (meningococcal, Pseudomonas)
- Coagulopathy in adults or Waterhouse-Friderichsen syndrome in children
- Thrombosis, embolism, adrenal infarction

Drugs
- Inhibit cortisol: ketoconazole, megestrol acetate
- Increase cortisol metabolism: rifampin, phenytoin, barbiturates, heparin, coumadin

Others
- Adrenoleukodystrophy
- Congenital adrenal hypoplasia (impaired steroidogenesis)
- Familial glucocorticoid deficiency or resistance

SECONDARY ADRENOCORTICAL INSUFFICIENCY
- inadequate pituitary ACTH secretion
- multiple etiologies (see Hypopituitarism, E20), including withdrawal of exogenous steroids

Adapted from: Salvatori R. JAMA 2005;294:2481-2488

Treatment
- acute condition – can be life-threatening
  - IV NS in large volumes (2-3 L); add D5W if hypoglycemic from adrenal insufficiency
  - hydrocortisone 50-100 mg IV q6-8h for 24h, then gradual tapering
  - identify and correct precipitating factors
- maintenance
  - hydrocortisone 15-20 mg total daily dose, in 2-3 divided doses, highest dose in the AM
  - Florinef® (fludrocortisone, synthetic mineralocorticoid) 0.05-0.2 mg PO daily if mineralocorticoid deficient increase dose of steroids 2-3 fold for a few days during moderate-severe illness (e.g. with vomiting, fever)
- major stress (e.g. surgery, trauma) requires 150-300 hydrocortisone IV daily divided into 3 doses
- medical alert bracelet and instructions for emergency hydrocortisone/dexamethasone IM/SC injection
Adrenal Medulla

Catecholamine Metabolism

- Catecholamines are synthesized from tyrosine in postganglionic sympathetic nerves (norepinephrine) and chromaffin cells of adrenal medulla (epinephrine).
- Broken down into metanephrines and other metabolites (VMA, HVA) and excreted in urine.

Pheochromocytoma

Definition

- Rare catecholamine secreting tumor derived from chromaffin cells of the sympathetic system.
- Most commonly a single tumor of adrenal medulla.
- Rare cause of HTN (<0.2% of all hypertensives).

Epidemiology

- Most cases sporadic (80%).
- Familial: associated with multiple endocrine neoplasia II (MEN IIA and IIB) (50% penetrance; i.e. 50% of people with the mutation get pheochromocytoma), von Hippel-Lindau (10-20% penetrance), paraganglioma (20% penetrance), or neurofibromatosis type 1 (0.1-5.7% penetrance).

Etiology and Pathophysiology

- Tumors, via unknown mechanism, able to synthesize and release excessive catecholamines.

Clinical Features

- 50% suffer from paroxysmal HTN; the rest have sustained HTN.
- Classic triad: episodic "pounding" headache, palpitations/tachycardia, diaphoresis.
- Other symptoms: tremor, anxiety, chest or abdominal pain, N/V, visual blurring, weight loss, polyuria, polydipsia.
- Other signs: orthostatic hypotension, papilledema, hyperglycemia, dilated cardiomyopathy.
- Symptoms may be triggered by stress, exertion, anesthesia, abdominal pressure, certain foods (especially tyramine containing foods).

Investigations

- Increased catecholamine metabolites (metanephrines) and free catecholamines.
- Plasma metanephrines if available (most sensitive).
- Cut-off values will depend on assay used.

- CT abdomen if negative, whole body CT and meta-iodo-benzoguanidine (MIBG) scintigraphy, Octreoscan, or MRI.

Treatment

- Surgical removal of tumor (curative) with careful pre- and post-operative ICU monitoring.
- Adequate pre-operative preparation.
  - $\alpha$-blockade for BP control: phenoxybenzamine (10-21 d pre-operative), IV phentolamine (perioperative, if required).
  - $\beta$-blockade for HR control once $\alpha$ blocked for a few days.
  - Metyrosine (catecholamine synthesis inhibitor) + phenoxybenzamine or prazosin.
  - Volume restoration with vigorous salt-loading and fluids.
- Rescreen urine 1-3 mo post-operatively.
- Screen urine in first degree relatives; genetic testing in patients <50 yr old.

Disorders of Multiple Endocrine Glands

Multiple Endocrine Neoplasm

- Neoplastic syndromes involving multiple endocrine glands.
- Tumors of neuroectodermal origin.
- Autosomal dominant inheritance with variable penetrance.
- Genetic screening for RET proto-oncogene on chromosome 10 has long-term benefit in MEN II.
  - Early cure and prevention of medullary thyroid cancer.

MTC: most common component, more aggressive and earlier onset than MEN IIa

3. IIb

<table>
<thead>
<tr>
<th>Thyroid</th>
<th>MTC</th>
</tr>
</thead>
</table>

Chronic constipation; megacolon

MRN for thyroid nodules → cytology

Investigations

- MEN I
  - laboratory
    - may consider genetic screening for MEN-1 mutation in index patients
      - if a mutation is identified, screen family members who are at risk
    - gastrinoma: elevated serum gastrin level (>200 ng/mL) after IV injection of secretin
    - insulinoma: reduced fasting blood glucose (hypoglycemia) with elevated insulin and C-peptide levels
    - glucagonoma: elevated blood glucose and glucagon levels
    - pituitary tumors: assess GH, IGF-1 and prolactin levels (for over-production), TSH, free T4, 8 AM cortisol, LH, FSH, bioavailable testosterone or estradiol (for underproduction due to mass effect of tumor)
    - hyperparathyroidism: serum Ca²⁺ and albumin, PTH levels; bone density scan (DEXA)
  - imaging
    - MRI for pituitary tumors, gastrinoma, insulinoma

- MEN II
  - laboratory
    - genetic screening for RET mutations in all index patients
      - if a mutation is identified, screen family members who are at risk
    - calcitonin levels (MTC); urine catecholamines and metanephrines (pheochromocytoma); serum Ca²⁺, albumin and PTH levels (hyperparathyroidism)
    - pentagastrin ± calcium stimulation test if calcitonin level is within reference range
    - FNA for thyroid nodules → cytology
  - imaging
    - CT or MRI of adrenal glands, metaiodobenzylguanidine (MIBG) scan for pheochromocytoma
    - octreoscan and/or radionuclide scanning for determining the extent of metastasis

Treatment

- MEN I
  - medical
    - proton pump inhibitor (PPI) for acid hypersecretion in gastrinoma
    - cabergoline or other dopamine agonists to suppress prolactin secretion
    - somatostatin for symptomatic carcinoid tumors
  - surgery for hyperparathyroidism, insulinoma, glucagonoma, pituitary tumors (if medical treatment fails for the latter)
    - trans-sphenoidal approach with prn external radiation

- MEN II
  - surgery for MTC
  - radiotherapy for pheochromocytoma

MEN I – Wermer’s Syndrome Affects the 3 Ps

Pituitary
Parathyroid
Pancreas
• MEN II
  • surgery for MEN IIA with pre-operative medical therapy
    • prostaglandin inhibitors to alleviate diarrhea associated with thyroid cancer
    • α-blocker for at least 10-21 d for pheochromocytoma pre-operatively
    • hydration, calcitonin, IV bisphosphonates for hypercalcemia

**Calcium Homeostasis**

- normal total serum Ca\(^{2+}\): 8.5-10.5 mg/dL (2.2-2.6 mmol/L)
- ionic/free Ca\(^{2+}\) levels: 4.6-5.25 mg/dL (1.15-1.31 mmol/L)
- serum Ca\(^{2+}\) is about 50% protein bound (mostly albumin)
- regulated mainly by two factors: parathyroid hormone (PTH) and vitamin D
- actions mainly on three organs: GI tract, bone, and kidney

### Table 27. Major Regulators in Calcium Homeostasis

<table>

</table>

### Figure 15. Parathyroid hormone (PTH) regulation

**Pseudohypercalcemia:** increased protein binding leading to an elevation in serum total Ca\(^{2+}\) without a rise in the ionized/free form, e.g. hyperalbuminemia from severe dehydration

**Primary Hyperparathyroidism:**
Increased PTH secretion commonly due to parathyroid adenoma, lithium therapy; less often parathyroid carcinoma or parathyroid hyperplasia

**Secondary Hyperparathyroidism:**
Partial resistance to PTH action leads to parathyroid gland hyperplasia and increased PTH secretion, often in patients with renal failure and osteomalacia (due to low or low normal serum calcium levels)

**Tertiary Hyperparathyroidism:**
Irreversible clonal outgrowth of parathyroid glands, usually in long-standing inadequately treated chronic renal failure on dialysis

**Primary Hyperparathyroidism** is the most common cause of hypercalcemia in healthy outpatients. Most commonly related to a solitary adenoma or less commonly multiple gland hyperplasia. Surgical excision acts as a definitive treatment and is recommended for patients who are symptomatic. For mild asymptomatic disease medical surveillance may be appropriate with annual serum calcium, creatinine, and BMD.

For asymptomatic patients surgery is recommended for those who meet ≥1 of the following criteria:
- Serum calcium concentration more than 1.0 mg/dL (0.25 mmol/L) above the upper limit of normal
- Creatinine clearance <60 mL/min
- BMD T-score <−2.5 at hip, spine, or distal radius, and/or previous fragility fracture
- Age <50 yr
**Hypercalcemia**

**Definition**
- total corrected serum Ca²⁺ >10.5 mg/dL (2.6 mmol/L) OR ionized Ca²⁺ >5.4 mg/dL (1.35 mmol/L)

**Approach to Hypercalcemia**
1. Is the patient hypercalcemic? (correct for albumin – see sidebar)
2. Is the PTH high/normal or low?
3. If PTH is low, is phosphate high/normal or low? If phosphate is high/normal is the level of vitamin D metabolites high or low?

**Figure 16. Differential diagnosis of hypercalcemia**

**Clinical Features**
- symptoms depend on the absolute Ca²⁺ value and the rate of its rise (may be asymptomatic)

**Table 28. Symptoms of Hypercalcemia**

<td>PUD</td>
<td>Renal failure (irreversible)</td>
<td>Gout</td>
<td>Weakness</td>
<td>Organic brain syndromes</td>
<td>Paresis</td>
</tr>
</tbody>
</table>

**Treatment**
- treatment depends on the Ca²⁺ level and the symptoms
- treat acute, symptomatic hypercalcemia aggressively

**Corrected Ca²⁺ (mmol/L) = measured Ca²⁺ + 0.02 (40 – albumin)**
- For every decrease in albumin by 10, increase in Ca²⁺ by 0.2
- Benign (less likely malignant): Ca²⁺ <2.75 mmol/L (11 mg/dL)
- Pathologic (more likely malignant): Ca²⁺ >3.25 mmol/L (13 mg/dL)
Hypocalcemia

Definition
- total corrected serum Ca\(^{2+}\) <8.5 mg/dL (2.2 mmol/L)

Table 30. Clinical Features of Hypocalcemia

</tr>
<tr>
<td>Psychiatric Sx:</td>
<td>emotional instability, anxiety, and depression</td>
</tr>
</tbody>
</table>

Approach to Hypocalcemia
1. Is the patient hypocalcemic?
2. Is the PTH high or low?
3. If PTH is high, is phosphate low or normal?
4. Is the Mg\(^{2+}\) level low?

Approach to Treatment
- correct underlying disorder
- mild/asymptomatic (ionized Ca\(^{2+}\) >3.2 mg/dL, 0.8 mmol/L)
  - treat by increasing dietary Ca\(^{2+}\) by 1000 mg/d
  - calcitriol 0.25 µg/d
- acute/asymptomatic hypocalcemia (ionized Ca\(^{2+}\) <2.8 mg/dL, 0.7 mmol/L)
  - immediate treatment required
  - IV calcium gluconate 1-2 g over 10-20 min followed by slow infusion if necessary
  - goal is to raise Ca\(^{2+}\) to low normal range (8.0-8.4 mg/dL, 2.0-2.1 mmol/L) to prevent symptoms but allow maximum stimulation of PTH secretion
- if PTH recovery not expected, requires long-term therapy with calcitriol and calcium
- do not correct hypocalcemia if asymptomatic and suspected to be transient
Hyperphosphatemia

Definition
- serum phosphate >4.1 mg/dL (1.45 mmol/L)

Table 31. Etiology of Hyperphosphatemia

<table>
<thead>
<tr>
<th>Increased Phosphate Load</th>
<th>Reduced Renal Clearance</th>
<th>Pseudohyperphosphatemia</th>

</tr>
<tr>
<td>Endogenous phosphate (tumor lysis syndrome, rhabdomyolysis, hemolysis, lactic and ketoacidosis)</td>
<td>Acromegaly</td>
<td>Hyperbilirubinemia</td>
</tr>
</tbody>
</table>

Clinical Features
- non-specific, include ectopic calcification, renal osteodystrophy

Treatment
- acute: hemodialysis if symptomatic
- chronic: low PO₄³⁻ diet, phosphate binders (e.g. CaCO₃ with meals)

Hypophosphatemia

Definition
- serum phosphate <2.4 mg/dL (0.85 mmol/L)

Table 32. Etiology of Hypophosphatemia

<table>
<thead>
<tr>
<th>Inadequate Intake</th>
<th>Renal Losses</th>
<th>Excessive Skeletal Mineralization</th>
<th>Shift into ICF</th>

<tr>
<td>Alcoholism</td>
<td>Hypophosphatemic rickets</td>
<td>Multiple myeloma</td>
<td></td>
</tr>
</tbody>
</table>

Symptoms usually present when phosphate <1.0 mg/dL (0.32 mmol/L)
Treat asymptomatic patients if phosphate <2.0 mg/dL (0.64 mmol/L)
Clinical Features
• non-specific (CHF, coma, hypotension, weakness, defective clotting)

Treatment
• treat underlying cause
  ▪ Oral PO₄³⁻: 2-4 g/d divided bid-qid (start at 1 g/d to minimize diarrhea)
  ▪ IV PO₄³⁻: only for severely symptomatic patients or inability to tolerate oral therapy

Hypermagnesemia

Definition
• serum magnesium >2.1 mg/dL (0.85 mmol/L)

Etiology
• AKI/CRF
• Mg²⁺-containing antacids or enemas
• IV administration of large doses of MgSO₄ (e.g., for preeclampsia; see Obstetrics, OB16)

Clinical Features
• drowsiness, hyporeflexia, respiratory depression, heart block, cardiac arrest

Treatment
• discontinue Mg²⁺-containing products
• IV calcium (Mg²⁺-antagonist) for acute reversal of magnesium toxicity
• dialysis if renal failure

Hypomagnesemia

Definition
• serum magnesium <1.7 mg/dL (0.70 mmol/L)

Etiology
• GI losses
  ▪ starvation/malabsorption
  ▪ vomiting/diarrhea
  ▪ alcoholism
  ▪ acute pancreatitis
• excess renal loss
  ▪ 2° hyperaldosteronism due to cirrhosis and CHF
  ▪ hyperglycemia
  ▪ hypokalemia
  ▪ hypercalcemia
  ▪ loop and thiazide-type diuretics
  ▪ nephrotoxic medications
  ▪ proton-pump inhibitors

Clinical Features
• seizures, paresis, Chvostek and Trousseau signs, ECG changes (widened QRS, prolonged PR, T-wave abnormalities), and arrhythmias including Torsades de pointes

Treatment
• treat underlying cause
• Mg²⁺ IM/IV; cellular uptake of Mg²⁺ is slow, therefore repletion requires sustained correction
• discontinue diuretics
  ▪ in patients requiring diuretics, use a K⁺-sparing diuretic to minimize magnesuria

Metabolic Bone Disease

Osteoporosis

Definition
• a condition characterized by decreased bone mass and microarchitectural deterioration of bone tissue with a consequent increase in bone fragility and susceptibility to fracture
• bone mineral density (BMD) ≥2.5 standard deviations below the peak bone mass for young adults (i.e., T-score ≤−2.5)
• osteopenia: BMD with T-score between −1.0 and −2.5

ETIOLOGY AND PATHOPHYSIOLOGY

Primary Osteoporosis
• primary type 1: most common in post-menopausal women, due to decline in estrogen, worsens with age
• primary type 2: occurs after age 75, seen in females and males at 2:1 ratio, possibly due to zinc deficiency

You will be unable to correct hypokalemia or hypocalcemia without first supplementing magnesium if patient hypomagnesemic

Online Clinical Tools
CAROC.pdf
FRAX
www.shef.ac.uk/FRAX/tool.aspx
Secondary Osteoporosis
- gastrointestinal diseases
  - gastrectomy
  - malabsorption (e.g., celiac disease)
  - chronic liver disease
- bone marrow disorders
  - multiple myeloma
  - lymphoma
  - leukemia
- endocrinopathies
  - Cushing's syndrome
  - hyperparathyroidism
  - hyperthyroidism
  - premature menopause
  - DM
- malignancy
  - secondary to chemotherapy
  - myeloma

Clinical Features
- commonly asymptomatic
- height loss due to collapsed vertebrae
- fractures: most commonly in hip, vertebrae, humerus, and wrist
- fragility fractures: fracture with fall from standing height
- Paget's disease: weakening of subchondral plates and expansion of intervertebral discs
- x-ray: vertebral compression and crush fractures, wedge fractures, "codfishing" sign
- pain, especially backache, associated with fractures

Approach to Osteoporosis
1. Assess risk factors for osteoporosis on history and physical
2. Decide if patient requires BMD testing with dual-energy x-ray absorptiometry (DEXA)
   - men
     - 10 yr fracture risk 10-20%
     - Medium Risk
     - 10 yr fracture risk <10%
     - Low Risk
     - 10 yr fracture risk >20%
     - OR
     - Prior fragility fracture of hip or spine
     - OR
     - More than one fragility fracture
   - women ≥65 yr or younger if presence of risk factors (Table 33)
   - and women ≥65 yr or younger if presence of risk factors (Table 33)
3. Initial investigations
   - assess risk factors for osteoporosis: calcium corrected for albumin, CBC, creatinine, ALP, TSH
   - also consider serum and urine protein electrophoresis, celiac workup, and 24 h urinary Ca
   - and excretion to rule out additional secondary causes
   - 25-OH-Vitamin D level should only be measured after 3-4 mo of adequate supplementation and should not be repeated if an optimal level ≥75 nmol/L is achieved
   - lateral thoracic and lumbar x-ray if clinical evidence of vertebral fracture
4. Assess 10 yr fracture risk by combining BMD result and risk factors (only if ≥50 yr)
   - 1) WHO Fracture Risk Assessment Tool (FRAX)
   - 2) Canadian Association of Radiologists and Osteoporosis Canada Risk Assessment Tool (CAROC)
   - approach to management guided by 10 yr risk stratification into low, medium, high risk
5. For all patients being assessed for osteoporosis, encourage appropriate lifestyle changes
   (see Table 35)

Figure 18. Physical examination test
Osteomalacia and Rickets

- **Rickets**: osteopenia with disordered calcification leading to a higher proportion of osteoid (unmineralized) tissue *prior* to epiphyseal closure (in childhood)
- **Osteomalacia**: osteopenia with disordered calcification leading to a higher proportion of osteoid (unmineralized) tissue *after* epiphyseal closure (in adulthood)

**Etiology and Pathophysiology**

**Vitamin D Deficiency**
- deficient uptake or absorption
  - nutritional deficiency
  - malabsorption: post-gastrectomy, small bowel disease (e.g. Celiac sprue), pancreatic insufficiency
- defective 25-hydroxylation
  - liver disease
  - anticonvulsant therapy
- loss of vitamin D binding protein
  - nephrotic syndrome
- defective 1-a-25 hydroxylation
  - hypoparathyroidism
  - renal failure
  - pathophysiology: leads to secondary hyperparathyroidism and hypophosphatemia

**Mineralization Defect**
- abnormal matrix
  - osteogenesis imperfecta
  - fibrogenesis imperfecta
  - axial osteomalacia
- enzyme deficiency
  - hypophosphatasia (inadequate ALP bioactivity)
- presence of calcification inhibitors
  - bisphosphonates, aluminum, high dose fluoride, anticonvulsants

- Conditions associated with abnormal matrix formation: Normal

- **Radiologic findings**
  - pseudofractures, fissures, narrow radiolucent lines – thought to be healed stress fractures or the result of erosion by arterial pulsation
  - loss of distinctness of vertebral body trabeculae; concavity of the vertebral bodies
  - changes due to secondary hyperparathyroidism: subperiosteal resorption of the phalanges, bone cysts, resorption of the distal ends of long bones
  - others: bowing of tibia, coxa profunda hip deformity
  - bone biopsy: usually not necessary but considered the gold standard for diagnosis

**Treatment**
- definitive treatment depends on the underlying cause
- vitamin D supplementation
- PO₄³⁻ supplements if low serum PO₄³⁻, Ca²⁺ supplements for isolated calcium deficiency
- bicarbonate if chronic metabolic acidosis
Renal Osteodystrophy

- changes to mineral metabolism and bone structure secondary to chronic kidney disease
- represents a mixture of four types of bone disease:
  - osteomalacia: low bone turnover combined with increased unmineralized bone (osteoid)
  - adynamic bone disease: low bone turnover due to excessive suppression of parathyroid gland
  - osteitis fibrosa cystica: increased bone turnover due to secondary hyperparathyroidism
  - mixed uremic osteodystrophy: both high and low bone turnover, characterized by marrow fibrosis and increased osteoid
- metastatic calcification secondary to hyperphosphatemia may occur

Pathophysiology

- metabolic bone disease secondary to chronic renal failure
- combination of hyperphosphatemia (inhibits 1,25(OH)2-Vit D synthesis) and loss of renal mass (reduced 1-α-hydroxylase)

Clinical Features

- soft tissue calcifications → necrotic skin lesions if vessels involved
- osteodystrophy → generalized bone pain and fractures
- pruritus
- neuromuscular irritability and tetany may occur
- radiologic features of osteitis fibrosa cystica, osteomalacia, osteosclerosis, osteoporosis

Investigations

- serum Ca2+ corrected for albumin, PO43-, PTH, ALP ± imaging (x-ray, BMD), ± bone biopsy

Treatment

- prevention
  - maintenance of normal serum Ca2+ and PO43+ by restricting PO43+ intake to 1 g OD
  - Ca2+ supplements; PO43+ binding agents (calcium carbonate, aluminum hydroxide)
  - vitamin D with close monitoring to avoid hypercalcemia and metastatic calcification

Paget’s Disease of Bone

Definition

- a metabolic disease characterized by excessive bone destruction and repair

Epidemiology

- a common disease: 5% of the population, 10% of population >80 yr old

Etiology and Pathophysiology

- postulated to be related to a slow progressing viral infection of osteoclasts, possibly paramyxovirus
- strong familial incidence
- initiated by increased osteoclastic activity leading to increased bone resorption; osteoblastic activity increases in response to produce new bone that is structurally abnormal and fragile

Differential Diagnosis

- primary bone lesions
  - osteogenic sarcoma
  - multiple myeloma
  - fibrous dysplasia
- secondary bone lesions
  - osteitis fibrosa cystica
  - metastases

Clinical Features

- usually asymptomatic (routine x-ray finding or elevated ALP)
- severe bone pain (e.g. pelvis, femur, tibia) is often the presenting complaint
- skeletal deformities: bowed tibias, kyphosis, frequent fractures
- skull involvement: headaches, increased hat size, deafness
- increased warmth over involved bones due to increased vascularity
- high output CHF
- hypercalcemia with immobilization
- osteosarcoma

Comparison of a Single Infusion of Zoledronic Acid with Risedronate for Paget’s Disease

- **Study:** Two identical, randomized, double-blind, actively controlled trials (combined for analysis).
- **Patients:** 357 men and women who were ≥30 yr and had radiologically confirmed Paget’s disease.
  - All but 4 patients had alkaline phosphatase levels that were more than twice the upper limit of normal.
- **Intervention:** One 15-min infusion of 5 mg of zoledronic acid compared with 60 d of oral risedronate (30 mg/d) with follow up at 6 mo.
- **Primary Outcome:** Rate of therapeutic response at 6 mo, defined as a normalization of alkaline phosphatase levels or a reduction of at least 75% in the total alkaline phosphatase excess.
- **Results:** At 6 mo, 96% of patients receiving zoledronic acid had a therapeutic response (169 of 176), as compared with 74.3% of patients receiving risedronate (127 of 171, p<0.001). Alkaline phosphatase levels normalized in 88.6% of patients in the zoledronic acid group and 57.9% of patients in the risedronate group (p<0.001). Zoledronic acid was associated with a shorter median time to a first therapeutic response (64 vs. 89 d, p<0.001).
- **Conclusion:** A single infusion of zoledronic acid produces more rapid, more complete, and more sustained responses in Paget’s disease than does daily treatment with risedronate.
Investigations
- laboratory
  - ↑↑ serum ALP (unless burnt out), Ca²⁺ normal or ↑, PO₄³⁻ normal
  - urinary hydroxyproline ↑ (indicates resorption)
- imaging
  - bone scan to evaluate the extent of disease
  - skeletal survey: involved bones are denser and expanded with cortical thickening
  - initial lesion may be destructive and radiolucent
  - multiple fissure fractures in long bones

Complications
- local
  - fractures, osteoarthritis
  - cranial nerve compression and palsies (e.g. deafness), spinal cord compression
  - osteosarcoma/sarcomatous change in 1-3%
    - indicated by marked bone pain, new lytic lesions and sudden increased ALP
- systemic
  - hypercalcemia and nephrolithiasis
  - high output CHF due to increased vascularity

Treatment
- symptomatic therapy (pain management)
- weight-bearing exercise
- adequate calcium and vitamin D intake to prevent development of secondary hyperparathyroidism
- treat medically if ALP >3x normal
  - bisphosphonates, e.g. alendronate 40 mg PO OD x 6 mo OR risedronate 30 mg PO OD x 3 mo OR zoledronic acid 5 mg IV per yr
  - calcitonin 50-100 U/d SC
- surgery for fractures, deformity, degenerative changes

Male Reproductive Endocrinology

Androgen Regulation
- negative feedback may occur by androgens directly or after conversion to estrogen
- testosterone (from Leydig cells) primarily involved in negative feedback on LH and GnRH, whereas inhibin (from Sertoli cells) suppresses FSH secretion

Tests of Testicular Function
- testicular size (lower limit = 4 cm x 2.5 cm)
- LH, FSH, total and/or bioavailable testosterone
- human chorionic gonadotropin (hCG) stimulation test
  - assesses ability of Leydig cell to respond to gonadotropin
- semen analysis
  - semen volume, sperm count, morphology, and motility
- testicular biopsy
  - indicated with normal FSH and azoospermia/oligospermia

Hypogonadism and Infertility
- see Urology, U33
- deficiency in gametogenesis or testosterone production

Etiology
- causes include primary (testicular failure), secondary (hypothalamic-pituitary failure), and idiopathic
- primary hypogonadism is more common than secondary
Table 38. Classification and Features of Hypogonadism

**Treatment**

- Testosterone replacement (improve libido, muscle mass, strength, hair growth, bone mass)
  - IM injection, transdermal testosterone patch/gel, oral
  - Side effects: acne, fluid retention, erythrocytosis, sleep apnea, benign prostatic hypertrophy, uncertain effects on cardiac events/mortality in older men
  - Contraindicated if history of prostate cancer, severe LUTS associated with BPH, uncontrolled or poorly controlled CHF
- GnRH agonist to restore fertility, if hypothalamic dysfunction with intact pituitary
  - Administered SC in pulsatile fashion using an external pump
- hCG + recombinant follicular stimulating hormone (rFSH) can be used to restore fertility in cases of either hypothalamic or pituitary lesions
- Testicular sperm extraction (TESE) or microscopic sperm extraction (MICROTESE) – only if testicular tissues are not functioning

**Other Causes of Male Infertility**

- Hereditary disorders: Kartagener syndrome, cystic fibrosis
- Anatomy: hypospadias, retrograde ejaculation
- Obstruction: vasal occlusion, vasal aplasia, vasectomy, seminal vesicle disease
- Sexual dysfunction: erectile dysfunction, premature ejaculation, infrequent coitus
- Surgery: TURP, radical prostatectomy, orchietomy

**DEFECTS IN ANDROGEN ACTION**

**Etiology**

- Complete androgen insensitivity (CAIS)
- Partial androgen insensitivity (PAIS)
- 5α-reductase deficiency
- Mixed gonadal dysgenesis
- Defects in testosterone synthesis
- Infertile male syndrome
- Undervirilized fertile male syndrome

**Etiology**

- Surgery: TURP, radical prostatectomy, orchiectomy
- Sexual dysfunction: erectile dysfunction, premature ejaculation, infrequent coitus
- Obstruction: vasal occlusion, vasal aplasia, vasectomy, seminal vesicle disease
- Anatomy: hypospadias, retrograde ejaculation

Adapted from: UpToDate, 2010; Cecil's Essentials of Medicine

Treatment
- appropriate gender assignment in the newborn
- hormone replacement or supplementation
- psychological support
- gonadectomy for cryptorchidism (due to increased risk for testicular cancer)
- reduction mammoplasty for gynecomastia

Erectile Dysfunction
- see Urology, U30

Gynecomastia

Definition
- true gynecomastia refers to benign proliferation of the glandular component of the male breast, resulting in the formation of a concentric, rubbery, firm mass extending from the nipple(s)
- pseudogynecomastia or lipomastia refers to enlargement of soft adipose tissue, especially seen in obese individuals and does not warrant further evaluation

Etiology

Physiologic
- puberty
- elderly (involutional)
- neonatal (maternal hormone)

Pathologic
- endocrinopathies: primary or secondary hypogonadism, hyperthyroidism, extreme hyperprolactinemia, adrenal disease
- tumors: pituitary, adrenal, testicular, breast, ectopic production of hCG
- chronic diseases: cirrhosis, renal, malnutrition (with refeeding)
- drugs: estrogens and estrogen agonists, spironolactone, ketoconazole, cimetidine, digoxin, chemotherapy, marijuana, alcohol
- congenital/genetic: Klinefelter’s syndrome, androgen insensitivity
- other: idiopathic, familial

Pathophysiology
- hormonal imbalance due to increased estrogen activity (increased production, or increased availability of estrogen precursors for peripheral conversion to estrogen) or decreased androgen activity (decreased androgen production, binding of androgen to sex hormone binding globulin (SHBG), or androgen receptor blockage)

History
- recent change in breast characteristics
- trauma to testicles
- mumps
- alcohol and/or drug use
- FHx
- sexual dysfunction
Physical Exam
- signs of feminization
- breast
  - rule out red flags suggesting breast cancer: unilateral, eccentric, hard, or fixed mass, skin dimpling or retraction, and nipple discharge or crusting
  - gynecomastia occurs concentrically around nipple, is not fixed to underlying tissue, and no discrete mass is palpable
- genito-urinary exam
- stigmata of liver or thyroid disease

Investigations
- laboratory: serum TSH, PRL, LH, FSH, testosterone, estradiol, LFTs, creatinine, hCG (if hCG is elevated need to locate the primary tumor)
- CXR and CT of chest/abdomen/pelvis (to locate neoplasm)
- testicular U/S to rule out testicular mass
- MRI of hypothalamic-pituitary region if pituitary adenoma suspected

Treatment
- initial observation for most men with gynecomastia
- medical
  - correct the underlying disorder, discontinue responsible drug
  - androgens for hypogonadism
  - anti-estrogens: tamoxifen, clomiphene
- surgical
  - usually required for macromastia; gynecomastia present for >1 yr (fibrosis is unresponsive to medication); or failed medical treatment and for cosmetic purposes

Female Reproductive Endocrinology

- see Gynecology, GY4
**Paraneoplastic Syndrome**

- clinical syndromes involving non-metastatic systemic effects that accompany malignant disease
- triggered by antibodies against neoplasm cross-reacting with normal tissue or by production of a physiologically active substance by the neoplasm
- commonly present with cancers of lung, breast, ovaries, or lymphatic system

**Table 40. Clinical Presentation**

References

Roff DS. Disorders that cause hypothyroidism. Rose BD (editor). Waltham: UpToDate. 2002.
Periodic Health Examination

- American Academy of Family Physicians (AAFP) represents 115,900 primary care physicians and student members nationwide
- approximately one in four of all office visits are made to family physicians (214 million office visits each yr)
- basis for recommendations is the analysis of scientific knowledge available as presented by the US Preventive Services Task Force (USPSTF) in the Guide to Clinical Preventive Services and ongoing updates
- recommendations are based on systematic analysis of scientific evidence
- most notable recommendation is the abolition of the annual physical exam; replaced by the PHE

Purpose of the PHE

- **primary prevention**: identify risk factors for common diseases; counsel patients to promote healthy behavior
- **secondary prevention**: presymptomatic detection of disease to allow early treatment and to prevent disease progression
- update clinical data
- enhance patient-physician relationship

AAFP Grading System (for recommendations before 2007)

- the recommendations include the examinations that should be offered (strongly recommend and recommend), those that should not be done (recommend against), those considered an option (no recommendation for or against), and those with insufficient evidence to recommend for or against
- **strongly recommend**: good quality evidence exists that demonstrates substantial net benefit over harm; the intervention is perceived to be cost effective and acceptable to nearly all patients
- **recommend**: although evidence exists that demonstrates net benefit, the benefit is only moderate in magnitude or the evidence supporting a substantial benefit is only fair; the intervention is perceived to be cost effective and acceptable to most patients
- **no recommendation for or against**: good or fair evidence exists of at least a small net benefit; cost effectiveness may not be known or patients may be divided about acceptability of the intervention
- **recommend against**: good or fair evidence that demonstrates no net benefit over harm
- **insufficient evidence to recommend for or against**: no evidence of even fair quality exists, or the existing evidence is conflicting

AAFP Grading System (for recommendations after 2007)

<table>
<thead>
<tr>
<th>Grade</th>
<th>Definition</th>
<th>Suggestions for Practice</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>The USPSTF recommends the service. There is high certainty that the net benefit is substantial</td>
<td>Offer or provide this service</td>
</tr>
<tr>
<td>B</td>
<td>The USPSTF recommends the service. There is high certainty that the net benefit is moderate or there is moderate certainty that the net benefit is moderate to substantial</td>
<td>Offer or provide this service</td>
</tr>
<tr>
<td>C</td>
<td>The USPSTF recommends selectively offering or providing this service to individual patients based on professional judgment and patient preferences. There is at least moderate certainty that the net benefit is small</td>
<td>Offer or provide this service for selected patients depending on individual circumstances</td>
</tr>
<tr>
<td>D</td>
<td>The USPSTF recommends against the service. There is moderate or high certainty that the service has no net benefit or that the harms outweigh the benefits</td>
<td>Discourage the use of this service</td>
</tr>
<tr>
<td>I Statement</td>
<td>The USPSTF concludes that the current evidence is insufficient to assess the balance of benefits and harms of the service. Evidence is lacking, of poor quality, or conflicting, and the balance of benefits and harms cannot be determined</td>
<td>Read the clinical considerations section of USPSTF Recommendation Statement. If the service is offered, patients should understand the uncertainty about the balance of benefits and harms</td>
</tr>
</tbody>
</table>

Patient-Centered Clinical Method
- Explore/define patient problems and decide on management together
- Consider both agendas and find common ground

Agendas in Family Medicine
- **Doctor’s Agenda**
  - History, physical, investigations, diagnosis, plan
- **Patient’s Agenda**
  - FIFE
    - Feelings: related to the illness, fears (how do you feel about what is happening?)
    - Ideas: and explanations of the cause (what do you think is going on?)
    - Function: the illness’ impact on daily life (how is it affecting your work or life?)
    - Expectations: of the doctor and the illness (what were you expecting at the visit?)

Adult Periodic Health Exam
- Male and female evidence-based preventive care checklist forms are available online at http://www.aafp.com

When Ordering Fasting Blood Work
- Routinely ordered as ≥12 h of fasting
- Remember, “fasting” means no food, no drinks (except small quantities of water), no gum, no smoking
- Prescription medications are okay unless otherwise specified
- Special care should be taken when ordering fasting blood work in elderly or other medically fragile patients

Note About PSA
- Routine PSA screening is currently not recommended
- PSA testing is used in ongoing surveillance and management of men with prostate cancer (see Urology, U25)

**Health Concern**

**AAFP Recommends**

**Grade**

**Healthy Diet**

Intensive behavioral dietary counseling for adult patients with hyperlipidemia and other known risk factors for cardiovascular and dia betic-related chronic disease. Intensive counseling can be delivered by primary care physicians or by other qualified professionals including dietitians and nutritionists (1996)

**Hearing Loss (Sensorineural)**

Screening for hearing loss in all newborn infants (2008)

**Hemoglobinopathies, Newborns**

Strongly recommends ordering screening tests for PKU, hemoglobinopathies, and thyroid function abnormalities in neonates (2007)

**Hepatitis B & C**

Screening for HBV and HCV infection in persons at high risks for infection. Also offering one-time screening for HCV infection to adults born between 1945 and 1965 (2013)

**HIV Infection, Adolescents and Adults**

That clinicians screen adolescents and adults ages 18 to 65 yr for HIV infection. Younger adolescents and older adults who are at increased risk should also be screened; refer to USPSTF guidelines for more detail

**HTN, Adults**

Screening for high blood pressure in adults aged 18 and older (2007)

**Immunization**

Immunizing all children 0-19 yr of age and all adults using AAFP guidelines unless contraindicated (2014)

**Folic Acid Supplementation, Women**

That all women planning or capable of pregnancy take a daily supplement containing 0.4-1.0 mg of folic acid (2009)

**Sexually Transmitted Diseases (STDs)**

High-intensity behavioral counseling of pregnant sexually transmitted diseases (STDs) for all sexually active adolescents and for adults at increased risk for STDs (2008)

**Skin Cancer, Behavioral Counseling**

Counseling children, adolescents, and young adults ages 10 to 24 yr who have fair skin about minimizing their exposure to ultraviolet radiation to reduce risk of skin cancer (2012)

**Tobacco Use, Adults**

Screening all adults for tobacco use and provide tobacco cessation interventions for those who use tobacco products (2009)

**Vision Screening, Children**

Vision screening for all children at least once between the ages of 3 and 5 yr to detect the presence of amblyopia or its risk factors (2011)

---

**Efficacy of Human Papillomavirus Vaccines – A Systematic Review**

*J. Gen. Intern. Med. 2009;24(10 Suppl)*

**Main Outcome:** Prevention of cytologically and/or histologically proven lesions (including LSIL, HSIL, VIN, VAIN, AIS, adenocarcinoma, site of the cervix, or the cervix associated with HPV infection).

**Results:** Bruised and quadrivalent vaccines reduced the rate of lesions in the cervix, vulva, vagina, and anogenital region with efficacy of 93% and 62%, respectively.

---

**Folic Acid Supplementation in Pregnancy (Joint SOGC-Motherisk Clinical Guideline)**

- To prevent neural tube defects in all women capable of becoming pregnant
- Low risk women (no personal health risks, planned pregnancy): 0.4-1.0 mg daily folic acid supplementation for at least 2-3 mo before conception and throughout pregnancy and postpartum period
- High risk women (health risks including epilepsy, insulin dependent DM, BMI >35, family history of NTDL, high risk ethnic group): at least 3 mo prior to conception until 10-12 wk post conception; daily folic acid supplementation with multivitamins with 5 mg folic acid
- From wk 12 post-conception until postpartum period: 0.4-1.0 mg of folic acid supplementation is sufficient
- Women with additional lifestyle issues (poor compliance with medications, no birth control, additional teratogenic substances): higher folic acid dose of 5 mg

---

**Prostate Cancer Mortality at 11 Year of Follow-Up**

*NEJM 2012;366:981-990*

**Study:** Updated ERSPC study – multicenter randomized trial of screening for prostate cancer using PSA.

**Patients:** 162,308 men, ages 55-69 from 8 different European countries.

**Intervention:** PSA-based screening

**Main Outcome:** mortality from prostate cancer

**Results:** After median follow-up of 11 yr, the RRR of death from prostate cancer was 21%. The ARR was 1.07 deaths/1000 men. NTDL = therefore to prevent one death from prostate cancer at 11 yr follow up, 1,055 men would need to be screened.

---

**Appropriate Use of Screening and Diagnostic Tests to Foster High-Value, Cost-Conscious Care**

*Ann Intern Med 2012;156:147-149*

**Suggested principles for providing high-value, cost-conscious care (see article Table 1 for specific examples):**

1. Diagnostic tests should not be performed if the results will not change management.
2. When the pretest probability of disease is low, the likelihood of a false-positive test result is higher than the likelihood of a true-positive result. False-positive results often lead to further testing, which may be expensive and potentially harmful (e.g., anxiety for patient, inappropriate treatment).
3. The true cost of a test includes not only the cost of the test itself but also the downstream costs incurred because the test was performed. These include the costs of subsequent testing, treatment, or follow-up.

**See Choosing Wisely - a campaign to help physicians and patients make smart and effective choices to ensure high-quality care.** http://www.choosingwisely.org.

- more detailed recommendations: Breast Cancer FM4, Colorectal Cancer FM4, Osteoporosis FM47, Obesity FM7

Breast Cancer Screening Guidelines

2013 Recommendations on Screening for Breast Cancer in Average-Risk Women (USPSTF)

- average-risk women: women age 40-74 with no personal history of breast cancer, history of breast cancer in 1st degree relatives, known mutations of the BRCA1/BRCA2 genes or previous exposures of the chest wall to radiation

Mammography

- age <50: recommend that decision to conduct screening mammography should be individualized and take into account patient context including her risks as well as values regarding specific benefits and harms (Grade C)
- age 50-74: recommend routine screening q2yr (Grade B)
- age 75+: current evidence is insufficient to assess benefits and harms of screening mammography (Grade I)

Magnetic Resonance Imaging

- current evidence insufficient to assess benefits and harms of MRI or digital mammography as screening modalities for breast cancer (Grade I)

Clinical Breast Examination

- current evidence insufficient to assess benefits and harms of CBE for women age 40 and older (Grade I)

Breast Self-Examination

- AAFP recommends against clinicians teaching women CBE (Grade D)

Prevention Medication

- AAFP recommends that clinicians engage in shared, informed decision making with women who are at increased risk for breast cancer about medications to reduce their risk
- for women who are at increased risk for breast cancer and at low risk for adverse medication effects, clinicians should offer to prescribe risk-reducing medications such as tamoxifen or raloxifene (Grade B)

BRCA Mutation Testing

- the AAFP recommends that primary care providers screen women who have family members with breast, ovarian, tubal, or peritoneal cancer with one of several screening tools designed to identify a family history that may be associated with an increased risk for potentially harmful mutations in breast cancer susceptibility genes (BRCA1 or BRCA2)
- women with positive screening results should receive genetic counseling and, if indicated after counseling, BRCA testing (Grade B)
- for more information on breast cancer and benign breast lesions, see General Surgery, GS54

Colorectal Cancer Screening Guidelines

- recommendations for average risk individuals (asymptomatic, no family history of UC, polyps, or CRC)
  - note: individuals with a personal history of cancer or adenomatous polyps should be followed by a surveillance regimen (screening guidelines are not applicable)
  - the AAFP recommends screening for CRC using fecal occult blood testing (FOBT), sigmoidoscopy, or colonoscopy, in adults 50-75 yr with the following intervals (Grade A recommendation)
    - annual screening with high-sensitivity FOBT
    - sigmoidoscopy every 5 yr, with high-sensitivity FOBT q3yr
    - screening colonoscopy q10yr
  - the AAFP recommends against routine screening for CRC in adults 76-85 yr (Grade C) and 85+ (Grade D)
• the USPSTF recommends against the use of aspirin or NSAIDs for the primary prevention of CRC (Grade C)
• the AAFP concludes that the evidence is insufficient to assess the benefits and harms of CT colonography and fecal DNA testing as screening modalities for CRC (Grade I recommendation)
• the AAFP recommends offering genetic testing for Lynch syndrome to patients diagnosed with CRC to reduce morbidity and mortality in relatives
  - genetic testing should be offered to 1st degree relatives of patients with Lynch syndrome, and those positive for Lynch syndrome should be offered earlier and more frequent CRC screening
• for more information on colorectal neoplasms, see General Surgery, GS33

Health Promotion and Counseling

• health promotion is the most effective preventive strategy
• 40–70% of productive life lost annually is preventable
• there are several effective ways to promote healthy behavioral change, such as discussions appropriate to a patient's present stage of change
• for more information about motivational interviewing, see http://www.motivationalinterviewing.org

Nutrition

General Population
- Key recommendations
  - choose foods that provide more potassium, calcium, vitamin D, and dietary fiber; these include vegetables, fruits, whole grains, and milk/milk products
- Sodium Intake
  - < 2,300 mg/d
  - further reduce intake to <1,500 mg/d in 51+ yr, those of any age who are African American, or have HTN, DM, or CKD (this recommendation applies to about 50% of the US population, including children)
- Fats
  - consume <10% of calories from saturated fatty acids (replace with MUFA and PUFA)
  - consume <300 mg per d of dietary cholesterol
  - limit trans fatty acid consumption (especially synthetic sources of trans fats, such as partially hydrogenated oils)
- Vegetables and Fruits
  - Increase vegetable and fruit intake; favor a variety of vegetables (dark-green, red, and orange), beans, and peas
- Grains
  - consume at least 50% of all grains as whole grains (replace refined grains with whole grains)
- Dairy
  - increase dairy intake overall (milk, yogurt, cheese, or alternatively fortified soy beverages), and favor fat-free or low-fat products
- Proteins
  - eat a variety of protein foods (seafood, lean meat and poultry, eggs, beans/peas, soy products, unsalted nuts/seeds)
  - try to increasingly substitute a variety of seafood in place of meat and poultry
  - replace protein foods that are higher in solid fats with others with a lower solid fat content and/or are a source of oils
- Refined Foods
  - reduce the intake of calories from solid fats and added sugars
  - limit the consumption of refined grain foods that also contain solid fats, added sugars, and sodium

Handy Serving Size Comparisons
- 3 oz meat, fish, poultry → palm of hand
- 1 cup dairy (milk/yogurt) → size of fist
- Bread/grains → one slice, palm of hand
- ½ cup rice/pasta → one hand cupped
- 1 cup of fruit/vegetables → two cupped hands
- 1 oz cheese → full length of thumb
- 1 tsp oil/butter → tip of thumb
- Nuts/chips/snacks → palm covered

Energy Content of Food
- Carbohydrates 4 kcal/g
- Protein 4 kcal/g
- Fat 9 kcal/g
- Ethanol 7 kcal/g

Calculating Total Daily Energy Expenditure (TDEE)
- Roughly 35 kcal/kg/d
- Varies by age, weight, sex, and activity level
- Average 2000-2100 kcal/d for women; 2700-2900 kcal/d for men
**Family Medicine Health Promotion and Counseling**

- recommendations for specific population groups
  - **Women Capable of Becoming Pregnant**
    - choose foods rich in heme iron (more readily absorbed), and enhancers of iron absorption (e.g. vitamin C-rich foods)
    - consume at least 400 µg/d of folic acid (from foods and supplements) in addition to food forms of folate from a varied diet
  - **Pregnant or Breastfeeding Women**
    - consume 8-12 oz of seafood/wk (limit white albacore tuna to 6 oz/wk and do not consume tilefish, shark, swordfish, or king mackerel as they are high in methyl mercury)
    - take an iron supplement if pregnant, as recommended by your healthcare provider
  - **Individuals >50 yr**
    - consume foods fortified in vitamin B12 (e.g. fortified cereals) or use dietary supplements

- counsel on variety, portion size, and plate layout
- vitamins and minerals: see CDC-Vitamins and Minerals, available from: http://www.cdc.gov/nutrition/everyone/basics/vitamins/

<td></td>
</tr>
</tbody>
</table>

**MUFA** = monounsaturated fatty acids; **PUFA** = polyunsaturated fatty acids

### Obesity

- body mass index (BMI) = weight (kg)/height (m)² = weight (lbs)/height (in)² x 703; BMI is a poor predictor of obesity
- waist circumference (WC) = flexible tape placed on horizontal plane at level of iliac crest
  - should be measured in all adults to assess obesity-related health risks
  - WC measurement for individuals of BMI >35 kg/m² is not necessary (almost all individuals with this BMI will have an abnormal WC)

#### Table 4. Classification of Weight by BMI, Waist Circumference, and Associated Disease Risks in Adults

<table>

</tbody>
</table>

### Adverse Medical Consequences of Obesity

- Type 2 DM
- CAD
- Stroke
- HTN
- Gallbladder disease
- Non-alcoholic steatohepatitis
- Complications of pregnancy
- Dyslipidemia
- Osteoarthritis
- Sleep apnea
- Certain cancers
- CHF
- Low back pain
- Increased total mortality

### Burning Fat

3500 kcal of energy are used for every pound of human fat burned during activity

### Losing Weight

- Aim for caloric intake 500-1000 kcal/d less than total daily energy expenditure (TDEE)
- Results in 1-2 lb (0.5-1 kg) weight loss per wk
- Achieved by combination of increased activity and/or decreased caloric intake

### Low BMI Associations

- Osteoporosis
- Eating disorders
- Under-nutrition
- Pregnancy complications
Epidemiology
- more than one-third of U.S. adults (34.9%) are obese
- non-Hispanic blacks have the highest age-adjusted rates of obesity (47.8%) followed by Hispanics (42.5%), non-Hispanic whites (32.6%), and non-Hispanic Asians (10.8%)
- obesity is higher among middle age adults, 40-59 yr old (39.5%) than among younger adults, age 20-39 (30.3%) or adults over 60 or above (35.4%) adults
- overweight and obesity rates in children are directly proportional to screen time (see Exercise, FM9)
- only 10-15% of population consume <30% fat daily
- obese persons generally consume more energy-dense food which tends to be highly processed, micronutrient poor, and high in fats, sugars, or starch

AAFP Guidelines For Adults (2012)
- the AAFP recommends screening all adults for obesity; clinicians should offer or refer patients with a BMI of 30 kg/m² or higher to intensive, multicomponent behavioral interventions (Grade B recommendation)
- intensive, multicomponent behavioral interventions include behavioral management activities (12 to 26 sessions in the first yr) such as setting weight loss goals, improving diet/nutrition and increasing physical activity, addressing barriers to change, self-monitoring, and strategizing how to maintain lifestyle changes. For more information: http://www.ahrq.gov/clinic/uspstf10/obeseadult/obesesum.htm

AAFP Guidelines For Children and Adolescents (2010)
- the AAFP recommends that clinicians screen children aged 6 yr and older for obesity and offer them or refer them to comprehensive, intensive behavioral interventions to promote improvement in weight status (Grade B recommendation)
- the definitions for specific interventions (targeted to diet and physical activity) and intensity (>25 h with child and/or family over 6 mo) are noted at: http://www.ahrq.gov/clinic/uspstf10/childobes/chobesrs.htm#clinical

Dyslipidemia
- see Endocrinology, E2
- defined as abnormal elevation of plasma cholesterol or triglyceride levels
- increased risk associated with obesity, DM, alcohol use

Assessment
- measure fasting serum, LDL-C, HDL-C, and TG
- screen with full fasting lipid profile q1-3yr in males >40 yr, females >50 yr or who are menopausal, or any adults with additional CAD risk factors
- assess for presence of other CAD risk factors (smoking, DM, HTN, obesity)
- screen for secondary causes: hypothyroidism, CKD, DM, nephrotic syndrome, liver disease
- risk category
  - estimate using the model for 10 yr CAD risk developed from the Framingham data (Framingham Risk Score – FRS)
  - FRS calculated based on the following factors: gender, age, HDL-C, total cholesterol, sBP, smoking, DM
    - if positive family Hx of CVD in a first degree relative before age 60 then multiply 10 yr CVD risk (%) x 2
    - to be completed for men age 40-75, and women age 50-75 q3-5yr
  - cardiovascular age calculated as patient's age + the difference between his or her estimated remaining life expectancy
    - used to increase adherence to therapy and reaffirm positive effect of following therapy
  - primary target of therapy is LDL-C levels; the alternate primary targets are apolipoprotein B (apo B) and non-HDL-C (not used widely yet)
  - optional secondary targets once LDL-C/apo B is at target include TC: HDL-C ratio, apo B/apo AI ratio, hs-CRP (used more for risk stratification of CAD), non-HDL-C, and serum TG levels
- emerging risk factors (from Framingham group)
  - lipoprotein a
  - metabolic syndrome
  - genetic risk
  - hormone replacement therapy
  - infectious agents

Pharmacotherapy for Obesity
- Orlistat: gastrointestinal lipase inhibitor, reduces fat absorption by 30% by inhibition of pancreatic lipase
- Orlistat is associated with several adverse effects and not approved for clinical use longer than 2 yr
- Orlistat should be avoided in people with inflammatory or chronic bowel disease

Hyperlipidemia Signs
- Atheromatous plaques in blood vessel walls
- Xanthomas: plaques or nodules composed of lipid-laden histiocytes in the skin (especially the eyelids)
- Tendinous xanthoma: lipid deposit in tendon (especially Achilles)
- Corneal arcus (arcus senilis): lipid deposit in cornea
- LDL cannot be calculated when TG ≥4.5 mmol/L

Safety of Statins: An Update
- Therapeutic Advances in Drug Safety 2012;3:133-144
- Trials have shown that statin therapy slightly increases the incidence of DM; however, the absolute risk is small. Relative to the reduction in coronary events, the clinical significance is not great enough to recommend against their use.
Management

- intensity and type of treatment is guided by “risk category” assigned
  1. health behaviors (can decrease LDL-C by up to 10%)
     - smoking cessation: probably the most important for preventing CAD
     - dietary modification: reduce saturated fats, refined sugars, alcohol; increase fruits, vegetables, and fiber
     - physical activity: at least 150 min of moderate to vigorous intensity aerobic exercise per week
     - employ consistent lifestyle modifications for at least 3 mo before considering drug therapy; high risk patients should start treatment immediately with concurrent health behavior interventions
  2. pharmacologic therapy (can decrease LDL-C by up to 40%)
     - for a comparison of dyslipidemia medications, see Endocrinology, E5
     - statins (HMG-CoA reductase inhibitors)
       - currently recommended as 1st line monotherapy following unsuccessful lifestyle modifications
       - risks: myopathy and hepatotoxicity – must follow LFTs q6-12mo
     - other agents: bile acid sequestrants, niacinic acid, fibrates, cholesterol absorption inhibitors (e.g. ezetimibe)
     - after initiating drug therapy
       - monitor ALT, AST, CK, Cr at baseline then 6 wk later for signs of transaminitis or myositis; tolerate rise in CK up to 10 times upper limit of normal if asymptomatic, or serum creatinine of ≤25%; repeat ALT, AST, and CK with lipid blood work
       - fasting lipids should be measured at 3 mo
     - if adequate response is achieved, evaluate fasting lipids q6-12mo
     - isolated hypertriglyceridemia (does not increase your cardiovascular risk)
       - normal HDL-C and TC, elevated TG
       - mild ≥2.2 mmol/L (≥85 mg/dL); marked ≥5.6 mmol/L (≥217 mg/dL)
       - principal therapy is lifestyle modification
         - weight loss, exercise, avoidance of smoking and alcohol, effective blood glucose control in diabetics, increased omega-3 fatty acid intake
         - severe hypertriglyceridemia (typically ≥100 mmol/L [≥387 mg/dL]) is associated with an increased risk of acute pancreatitis
     - drug therapy (used to prevent pancreatitis, NOT CVD)
       - nicotinic acid
       - fibrates

Epidemiology

- 25% of the population exercises regularly, 50% occasionally, 25% are sedentary
- screen time (time spent watching TV/movies, playing video games, or using the computer) has been increasing steadily in the last several years, while time spent being physically active has been decreasing
- current recommendation from international pediatric societies is that children (>2 yr old) should limit their screen time to less than 2 h/d
Management

- assess current level of fitness, motivation, and access to exercise
- encourage warm up and cool down periods to allow transition between rest and activity and to avoid injuries
- exercise with caution for patients with CAD, DM (risk of hypoglycemia), exercise-induced asthma
- patients with known CAD should have cardiac assessment prior to commencing exercise
- AAFP recommends that physicians counsel patients to meet recommended levels of physical activity
  - adults: ≥150 min of moderate- to vigorous-intensity aerobic physical activity per wk, or ≥ 75 min of vigorous activity, or an equivalent combination of moderate-to-vigorous activity, in bouts of ≥10 min. For additional benefits, can increase to 300 min of moderate intensity or 150 min of vigorous intensity aerobic physical activity
    - moderate-intensity: brisk walking, bike riding
    - vigorous-intensity: jogging, cross-country skiing
  - children and adolescents: ≥60 min of moderate-to-vigorous-intensity aerobic physical activity daily (with vigorous activity at least 3x wk)
  - older adults (65 yr and older): same as adult guidelines; in addition individuals with poor mobility should perform physical activities to aid with balance and prevent falls
    - when older adults cannot meet the adult guidelines due to chronic illness, they should be as physically active as their abilities and conditions allow
  - every age group: muscle and bone strengthening activities using major muscle groups,
    - adults and older adults: ≥2 d/wk
    - children and adolescents: ≥3d/wk
- benefits of exercise
  - reduces risk of premature death, heart disease, stroke, HTN, certain types of cancer, type 2 DM, osteoporosis, and overweight/obesity
  - leads to improved fitness, strength, and mental health (morale and self-esteem)

Smoking Cessation

Epidemiology

- smoking is the single most preventable cause of premature illness and death
- each yr, 440,000 deaths in the US are attributable to smoking or second-hand smoking exposure
- 70% of smokers see a physician each year, but only 28% receive advice or assistance from their physician regarding quitting
- of the 46 million current US smokers, 70% say they would like to quit, but without help only 5% actually quit
- most smokers try to quit on their own (without using evidence-based approaches), and >95% relapse

Management

- general approach
  - the AAFP encourages family physicians to ask about smoking, and then to act to help them quit
  - identify tobacco users; elicit smoking habits, previous quit attempts and results
- AAFP Clinical Preventive Service Recommendation - Tobacco Use
  - clinicians should screen all adults for tobacco use and provide tobacco cessation interventions for those who use tobacco products (Grade A recommendation, 2009)
  - clinicians should screen all pregnant women for tobacco use and provide 5-15 min of smoking cessation counseling using messages and self-help materials tailored for pregnant smokers (Grade A recommendation, 2003)
  - every smoker should be offered treatment
    - combining counseling and smoking cessation medication is more effective than either alone (Grade 1A)
    - individual, phone, and group counseling are effective modalities of counseling (effectiveness increases with treatment intensity); combining two or more components is especially effective
    - make patient aware of withdrawal symptoms
      - low mood, insomnia, irritability, anxiety, difficulty concentrating, restlessness, decreased heart rate, increased appetite
    - ≥4 counseling sessions >10 min each with 6-12 mo follow-up yields better results
    - 14% abstinence with counseling vs. 10% without counseling
    - approach depends on patient's stage of change (see Motivational Strategies for Behavioral Change, FM6)
• willing to quit
  • provision of social support, community resources (self-help, group, helpline, web-based strategies)
  • pregnant patients: counseling is recommended as 1st line treatment, as there is insufficient data regarding safety and effectiveness of nicotine replacement therapies (NRT) in this population

• pharmacologic therapy
  1. nicotine replacement therapy
     • 19.7% abstinent at 12 mo with NRT vs. 11.5% for placebo
     • no difference in achieving abstinence for different forms of NRT
     • reduces cravings and withdrawal symptoms without other harmful substances that are contained in cigarettes
     • use with caution: immediate post-MI, serious/worsening angina, serious arrhythmia
     • advise NO smoking while using NRT
  2. antidepressants (note: mode of action appears to be independent of antidepressant effect)
     • Bupropion SR (Zyban*)
       • 21% abstinent at 12 mo vs. 8% for placebo
       • no advantage for NRT vs. bupropion (similarly effective)
     • Nortriptyline (2nd line, not officially approved for smoking cessation)
       • effectiveness comparable to bupropion
  3. Varenicline (Champix®)
     • partial nicotinic receptor agonist (to reduce cravings) and partial competitive nicotinic receptor antagonist (to reduce the response to smoked nicotine)
     • more effective than bupropion (23% abstinent from 9-52 wk with varenicline vs. 16% for bupropion vs. 9% with placebo)

Table 7. Pharmacologic Treatments for Smoking Cessation

<table>
<thead>
<tr>
<th>Drug</th>
<th>Mechanism</th>
<th>Dosage</th>
<th>Prescribing*</th>
<th>Contraindications</th>
</tr>
</thead>
</table>
| Bupropion          | Inhibits re-uptake of dopamine and/or noradrenaline, competitive antagonist of norepinephrine | 1. 150 mg qAM x 3 d
                       |                                                | 2. Then 150 mg bid x 7-12 wk
                       |                                                | 3. For maintenance consider 150 mg bid for up to 6 mo         | Seizure disorder
|                    |                                                | 1. Decide on a quit date
                       |                                                | 2. Continue to smoke for first 1-2 wk of treatment and then completely stop (therapeutic levels reached in 1 wk) | Eating disorder
|                    |                                                | 3. Then 12 wk therapeutic dose of 70-100 mg daily                  | Simultaneous use of MAOI use in past 14 d | Major depression
| Nortriptyline (2nd line) | Inhibits adrenergic re-uptake (may also inhibit serotonin/histamine re-uptake) | 1. Initial titration before the quit attempt (10-20 d)
                       |                                                | 2. Then 12 wk therapeutic dose of 70-100 mg daily                  | Usually prescribed when 1st line treatments have been unsuccessful | Acute recovery period following MI
|                    |                                                | 3. Continue to smoke for first wk of treatment and then completely stop (therapeutic levels reached in 1 wk) | MAOI use in past 14 d | Following MI
| Varenicline        | Partial nicotinic receptor agonist, and partial nicotinic receptor competitive antagonist | 1. 0.5 mg qAM x 3 d
                       |                                                | 2. Then 0.5 mg bid x 4 d
                       |                                                | 3. Then 1 mg bid x 12 wk ± additional 12 wk as maintenance       | Caution with pre-existing psychiatric condition

Table 6. Types of Nicotine Replacement Therapy

<table>
<thead>
<tr>
<th>Type</th>
<th>Dosage</th>
<th>Comment</th>
<th>Side Effects</th>
</tr>
</thead>
</table>
| Nicotine Gum (OTC)  | 2 mg if < 25 cig/d
                       | 4 mg if > 25 cig/d
                       | 1 piece q1-2h for 1-3 mo (max 24 pieces/d)  | Chew until “peppery” taste then “park” between gum and cheek to facilitate absorption
                       | Continue to chew park intermittently for 30 min | Mouth soreness, Hiccups, Dyspepsia, Jaw ache
| Nicotine Patch (OTC)| Use for 8 wk
                       | 21 mg/d x 4 wk
                       | 14 mg/d x 2 wk
                       | 7 mg/d x 2 wk                             | Start with lower dose if < 10 cig/d
                       | Change patch q24h and alternate sides      | Skin irritation, Insomnia, Palpitations, Anxiety
| Nicotine Inhaler (OTC)| 6-16 cartridges/d
                           | for up to 12 wk                             | Nicotine inhaled through mouth, absorbed in mouth and throat not in lungs | Local irritation, Coughing
| Nicotine Nasal Spray (Rx)| Never form of NRT                     | Nevers form of NRT                           | Local irritation, coughing

*May be used in combination with nicotine replacement therapy.
unwilling to quit

- motivational intervention (5 Rs)
  1. Relevance to patient
     - relevant to patient's disease status or risk, family or social situation (e.g. having children in the home), health concerns, age, gender
  2. Risks of smoking
     - short-term: SOB, asthma exacerbation, impotence, infertility, pregnancy complications, heartburn, URTI
     - long-term: MI, stroke, COPD, lung CA, other cancers
     - environmental: higher risk in spouse/children for lung CA, SIDS, asthma, respiratory infections
  3. Rewards: benefits
     - improved health, save money, food tastes better, good example to children
  4. Roadblocks: obstacles
     - fear of withdrawal, weight gain, failure, lack of support
  5. Repetition
     - reassure unsuccessful patients that most people try many times before successfully quitting (average number of attempts before success is 7)
  - recent quitter
     - highest relapse rate within 3 mo of quitting

- recent quitter

- minimal practice: congratulate on success, encourage ongoing abstinence, review benefits and problems

Alcohol

- see Psychiatry, PS19

Definition
- diagnostic categories occur along a continuum

Epidemiology
- 10-15% of patients in family practice are problem drinkers
- more likely to miss diagnosis in women or elderly patients with high socioeconomic status

Assessment
- screen for alcohol dependence with CAGE questionnaire
  - if CAGE positive, explore with further questions for alcohol abuse/dependence
- assess drinking profile
  - setting, time, place, occasion, with whom
  - impact on: family, work, social
  - quantity-frequency history
    - how many drinks per d?
    - how many days per wk?
    - maximum number of drinks on any 1 d in the past month?
  - if identified positive for alcohol problem
    - screen for other drug use
    - identify medical-psychiatric complications
    - ask about drinking and driving
    - ask about past recovery attempts and current readiness for change

Investigations
- GGT and MCV for baseline and follow-up monitoring
- AST, ALT (usually AST:ALT approaches 2:1 in an alcoholic)
- CBC (anemia, thrombocytopenia), INR (decreased clotting factor production by liver)

Management
- intervention should be consistent with patient's motivation for change
- regular follow-up is crucial
- 10% of patients in alcohol withdrawal will have seizures or delirium tremens
- Alcoholics Anonymous/12-steps program
- outpatient/day programs for those with chronic, resistant problems
- family treatment (Al-Anon, Alateen, screen for spouse/child abuse)
- in-patient program if
  - dangerous or highly unstable home environment
  - severe medical/psychiatric problem

- standard drink equivalents
  - one standard drink = 14 g of pure alcohol
    - Beer (5% alcohol) = 12 oz
    - Wine (12-17% alcohol) = 5 oz
    - Fortified wine = 3 oz
    - Hard liquor (40%) = 1.5 oz

- CAGE questionnaire
  - C Have you ever felt the need to CUT down on your drinking?
  - A Have you ever felt ANNOYED at criticism of your drinking?
  - G Have you ever felt GUILTY about your drinking?
  - E Have you ever had a drink first thing in the morning to steady your nerves or get rid of a hangover? (EYE OPENER)

  - ≥2 for men or ≥1 for women suggests possibility of problem drinking (sensitivity 85%, specificity 89%)

- some adverse medical consequences of problem drinking
  - GI: gastritis, dyspepsia, pancreatitis, liver disease, bleeds, diarrhea, oral/oesophageal cancer
  - Cardiac: HTN, alcoholic cardiomyopathy
  - Neurologic: Wernicke-Korsakoff syndrome, peripheral neuropathy
  - Hematologic: anemia, coagulopathies
  - Other: trauma, insomnia, family violence, anxiety/depression, social/family dysfunction, sexual dysfunction, fetal damage
• addiction to drug that may require in-patient detoxification
• refractory to other treatment programs
  • pharmacologic
    • diazepam for withdrawal
    • disulfiram (Antabuse®): impairs metabolism of alcohol by blocking conversion of acetaldehyde to acetic acid, leading to flushing, headache, N/V, hypotension if alcohol is ingested
    • naltrexone: competitive opioid antagonist that reduces cravings and pleasurable effects of drinking
      • may trigger withdrawal in opioid-dependent patients

**Prognosis**
• relapse is common and should not be viewed as failure
• monitor regularly for signs of relapse
• 25-30% of abusers exhibit spontaneous improvement over 1 yr
• 60-70% of individuals with jobs and families have an improved quality of life 1 yr post-treatment

---

### Common Presenting Problems

#### Abdominal Pain

• see Gastroenterology, G4 and General Surgery, GS4

**Epidemiology**
• 20% of individuals have experienced abdominal pain within the last 6-12 mo
• 90% resolve in 2-3 wk
• only 10% are referred to specialists, of those <10% admitted to hospital

**Etiology**
• most common diagnosis is “nonspecific abdominal pain,” which has no identifiable cause and is usually self-limited
• GI disorders (e.g. PUD, pancreatitis, IBD, appendicitis, gastroenteritis, IBS, diverticular disease, biliary tract disease)
• urinary tract disorders (e.g. UTI, renal calculi)
• gynecological disorders (e.g. PID, ectopic pregnancy, endometriosis)
• cardiovascular disorders (e.g. CAD, AAA, ischemic bowel)
• other: medications (e.g. NSAIDs), alcohol, toxic ingestion, foreign body, psychogenic

**Pathophysiology**
• type of pain
  • somatic pain: sharp, localized pain
  • visceral pain: dull, generalized pain
• location of pain
  • epigastric (foregut): distal esophagus, stomach, proximal duodenum, biliary tree, pancreas, liver
  • periumbilical (midgut): distal duodenum to proximal 2/3 of transverse colon
  • hypogastric (hindgut): distal 1/3 of transverse colon to rectosigmoid region

**Investigations**
• guided by findings on history and physical
• possible blood work: CBC, electrolytes, BUN, Cr, amylase, lipase, AST, ALT, ALP, bilirubin, glucose, INR/PTT, tox screen, β-hCG
• imaging
  • CXR (for free air under the diaphragm) in setting of perforation in surgical abdomen
  • abdominal x-ray, KUB (consider: gas pattern, free air, kidney stones, constipation)
  • ultrasound (gallbladder disease, gynecological problems, liver disease, pancreatitis, diverticular disease, appendicitis)
  • CT scan (AAA, appendicitis)
• other tests
  • urinalysis
  • endoscopy (for peptic ulcers, gastritis, tumors, etc.)
  • *H. pylori* testing (urea breath test, serology, biopsy)

---

**Key Definitions for Alcohol**

**What is moderate alcohol consumption?** Moderate alcohol consumption is defined as up to 1 drink per d for women and up to 2 drinks per d for men.

**What is heavy or high-risk drinking?** Heavy or high-risk drinking is the consumption of more than 3 drinks on any day or more than 7 wk for women and more than 4 drinks on any day or more than 14 per wk for men.

**What is binge drinking?** Binge drinking is the consumption within 2 h of 4 or more drinks for women and 5 or more drinks for men.

Allergic Rhinitis

- see Otolaryngology, OT24

**Definition**
- inflammation of the nasal mucosa that is triggered by an allergic reaction

**Classification**
- seasonal
  - symptoms during a specific time of the year
  - common allergens: trees, grass and weed pollens, airborne molds
- perennial
  - symptoms throughout the year with variation in severity
  - common allergens: dust mites, animal dander, molds

**Etiology**
- increased IgE levels to certain allergens → excessive degranulation of mast cells → release of inflammatory mediators (e.g. histamine) and cytokines → local inflammatory reaction

**Epidemiology**
- affects approximately 40% of children and 20-30% of adults
- prevalence has increased in developed countries, particularly in the past two decades
- associated with asthma, eczema, sinusitis, and otitis media

**Assessment**
- identify allergens
- take an environmental/occupational history
- ask about related conditions (e.g. atopic dermatitis, asthma, sinusitis, and family history)

**Management**
- conservative
  - minimize exposure to allergens
  - most important aspect of management, often sufficient (may take months)
  - maintain hygiene, saline nasal rinses
- pharmacologic agents
  - oral antihistamines – first line therapy for mild symptoms
    - e.g. cetirizine (Reactine®), fexofenadine (Allegra®), loratadine (Claritin®)
  - intranasal corticosteroids for moderate/severe or persistent symptoms (>1 mo of consistent use to see results)
  - intranasal decongestants (use must be limited to <5 d to avoid rhinitis medicamentosa)
- allergy skin testing
  - reserved for severe cases unresponsive to pharmacologic agents
  - consists of periodic (usually weekly) subcutaneous injections of custom prepared solutions of one or more antigens to which the patient is allergic

Amenorrhea

- see Gynecology, G9

Anxiety

- see Psychiatry, PS10

**Epidemiology**
- 25-30% of patients in primary care settings have psychiatric disorders
- many are undiagnosed or untreated; hence the need for good screening
- high rate of coexistence of anxiety disorders and depression

**Screening**
- screening questions
  - Do you tend to be an anxious or nervous person?
  - Have you felt unusually worried about things recently?
  - Has this worrying affected your life? How?
Asthma/COPD

**Definition**

- **asthma**
  - chronic but reversible airway inflammation characterized by periodic attacks of wheezing, SOB, chest tightness, and coughing
  - airways hyper-responsive to triggers/antigens leading to acute obstructive symptoms by bronchoconstriction, mucous plugs, and increased inflammation
  - cannot be diagnosed at first presentation; called reactive airway disease until recurrent presentations
  - pulmonary function tests (PFTs) can be done from age 6 or when child able to follow instructions to do PFTs
  - peak flow meters are useful in the office and at home for monitoring
  - chronic obstructive pulmonary disease (COPD)
    - a group of chronic, progressive, expiratory lung diseases characterized by limited airflow with variable degrees of air sac enlargement and lung tissue destruction
    - emphysema and chronic bronchitis are the most common forms of COPD

**Assessment**

- associated symptoms
- risk factors
  - family history of anxiety or depression, past history of anxiety, stressful life event, social isolation, female, comorbid psychiatric diagnosis (e.g. depression)
- assess substance abuse, comorbid depression, stressful life events, trauma, suicidal ideation/self-harm
- to differentiate anxiety disorders, consider symptoms (panic attacks, specific situations/stressors, excessive worry about common concerns, repetitive thoughts and/or behaviors to neutralize the anxiety) and their duration

**Management**

- patient education: emphasize prevalence, good recovery rate of anxiety conditions
- lifestyle advice: decrease caffeine and alcohol intake, exercise, relaxation techniques, mindfulness strategies
- self-help materials, community resources (e.g. support groups)
- CBT: cognitive interventions, exposure therapy, etc.
- provide support to family and caregivers
- for pharmacotherapy, see Psychiatry, PS47

**Rule Out**

- Cardiac (post MI, arrhythmias)
- Endocrine (hyperthyroidism, DM, pheochromocytoma)
- Respiratory (asthma, COPD)
- Somatoform disorders
- Psychotic disorders
- Mood disorders (depression, bipolar)
- Personality disorder (OCPD)
- Drugs (amphetamines, thyroid preparations, caffeine, OTC for colds/decongestants, alcohol/benzodiazepine withdrawal)

**Differential Diagnosis of Anxiety Disorders**

- Panic disorder
- GAD
- Social Anxiety Disorder (previously Social Phobia)
- Agoraphobia
- Specific phobia
- Selective Mutism
- Separation Anxiety Disorder
- Other: AMC, mood disorder, psychotic disorder, OCD, PTSD

**Symptoms of GAD**

- Anxious, nervous, or worried
- No control over the worry
- Duration > 6 mo
- Irritability
- Concentration impairment
- Restlessness
- Energy decreased
- Sleep impairment
- Tension in muscles

**Table 8. Differentiating COPD from Asthma**

<table>

- Normal curve, obstructive curve, restrictive curve
- One second time marker

Benign Prostatic Hyperplasia

- ser{}um PSA: protein produced by prostatic tissue, see Urology, U25
- urinalysis to exclude UTI and for microscopic hematuria (common sign)

### Investigations
- urinalysis to exclude UTI and for microscopic hematuria (common sign)
- serum PSA: protein produced by prostatic tissue, see Urology, U25
  - values
    - <4.0 ng/mL: normal, but must take into account patient’s age and velocity of PSA increase
    - 4-10 ng/mL: consider measuring free/total PSA
    - >10 ng/mL: high likelihood of prostate pathology
- PSA testing is inappropriate in men with a life expectancy less than 10 yr or patients with prostatitis, UTI
- increased PSA in a younger man is more often due to cancer than other causes
- abnormal DRE or PSA should trigger further assessment
- decision to test PSA in an asymptomatic man should involve discussion about the risks and possible benefits
- other tests
  - Cr, BUN
  - post-void residual volume by ultrasound
  - renal ultrasound
  - patient voiding diary
- tests NOT recommended as part of routine initial evaluation include
  - cystoscopy
  - cytology
  - prostate ultrasound or biopsy
  - IVP
  - urodynamic studies

### Management

### More About Inhalers
- Aerosols (puffers=MDI, MDI + spacer) MDIs should be used with spacers to:
  - Reduce side effects
  - Improve amount inhaled
  - Increase efficiency of use
- Dry Powder Inhaler (discus, turbuhaler and diskhaler), they require deep and fast breathing (may not be ideal for children)
- Nebulizers can be used to convert liquid medications into a fine mist; recommended for use if contraindications to MDIs

### Differential Diagnosis of Wheezing
- Allergies, anaphylaxis
- Asthma, reactive airway disease
- GERD
- Infections (bronchitis, pneumonia)
- Obstructive Sleep Apnea
- COPD
- Less common: congestive heart disease, foreign body, malignancy, cystic fibrosis, vocal cord dysfunction

### Self-Management Asthma and COPD Education and Written Action Plan
- Education is a key component in management of asthma and COPD
- Guided self-management combining education, regular medical review, self-assessment, and written action plan have been shown to reduce hospitalizations, ED visits, and missed days at work or school
- Sample action plans available online: http://www.respiratoryguidelines.ca

### More About Asthma
- Leukotrienes (LTD4, LTE4, LTB4)
- *Lowering of the threshold for bronchial smooth muscle to spasmogen (contracting agent) or mediator (chemical substance)*

### More About COPD
- Tiotropium – Spiriva®
- Ipratropium/Albuterol – Combivent®
- Increased bronchial markings (chronic bronchitis) and chronic hyperinflation (emphysema) often co-exist, bullae
- COPD
- Obstructive Sleep Apnea
- Infections (bronchitis, pneumonia)
- GERD
- Asthma, reactive airway disease
- Allergies, anaphylaxis

### When prescribing salbutamol, watch out for signs of hypokalemia: lethargy, irritability, paresthesias, myalgias, weakness, palpitations, N/V, polyuria

### Table 8. Differentiating COPD from Asthma (continued)

</table>

Management

- referral to urologist if moderate/severe symptoms
- conservative: for patients with mild symptoms or moderate/severe symptoms considered by the patient to be non-bothersome
  - fluid restriction (avoid alcohol and caffeine)
  - avoidance/monitoring of certain medications (e.g. antihistamines, diuretics, antidepressants, decongestants)
  - pelvic floor/Kegel exercises
  - bladder retraining (scheduled voiding)
- pharmacological: for moderate/severe symptoms
  - $\alpha$-receptor antagonists (e.g. terazosin [Hytrin®], doxazosin [Cardura®], tamsulosin [Flomax®], alfuzosin [Xatral®])
    - relaxation of smooth muscle around the prostate and bladder neck
  - 5-alpha reductase inhibitor (e.g. finasteride [Proscar®])
    - only for patients with demonstrated prostatic enlargement due to BPH
    - inhibits enzyme responsible for conversion of testosterone into dihydrotestosterone (DHT) thus reducing growth of prostate
  - phytotherapy (e.g. saw palmetto berry extract, Pygeum africanum)
    - more studies required before this can be recommended as standard therapy
  - considered safe
- surgical
  - TURP (transurethral resection of the prostate), TUİP (transurethral incision of the prostate, for prostates <30 g)
  - absolute indications: failed medical therapy, intractable urinary retention, benign prostatic obstruction leading to renal insufficiency
  - complications: impotence, incontinence, ejaculatory difficulties (retrograde ejaculation), decreased libido

Bronchitis (Acute)

Definition

- acute infection of the tracheobronchial tree causing inflammation leading to bronchial edema and mucus formation

Epidemiology

- 5th most common diagnosis in family medicine, most common is URTI

Etiology

- 80% viral: rhinovirus, coronavirus, adenovirus, influenza, parainfluenza, respiratory syncytial virus (RSV)
- 20% bacterial: M. pneumoniae, C. pneumoniae, S. pneumoniae

Investigations

- acute bronchitis is typically a clinical diagnosis
- sputum culture/gram stain is not very informative
- CXR if suspect pneumonia (cough >3 wk, abnormal vital signs, localized chest findings) or CHF
- PFT with methacholine challenge if suspect asthma

Management

- primary prevention: frequent hand washing, smoking cessation, avoid irritant exposure
- symptomatic relief: rest, fluids (3-4 L/d when febrile), humidity, analgesics and antitussives as required
- bronchodilators may offer improvement of symptoms (e.g. salbutamol)
- current literature does not support routine antibiotic treatment for the management of acute bronchitis because it is most likely to be caused by a viral infection
- antibiotics may be useful if elderly, comorbidities, suspected pneumonia, or if the patient is toxic (see Antimicrobial Quick Reference, FM53)
- antibiotics in children show no benefit
**Chest Pain**

- see Cardiology and Cardiac Surgery, C4 and Emergency Medicine, ER21

</table>

*Emergent

**Investigations**

- ECG, CXR, and others if indicated (cardiac enzymes, d-dimers, liver function tests [LFTs], etc.)
- refer to ED if suspect serious etiology (e.g. aortic dissection, MI)

**Management of Common Causes of Chest Pain**

- angina/ischemic heart disease
  - nitroglycerin (NTG): wait 5 min between sprays and if no effect after 3 sprays, send to ED
  - myocardial infarction
    - ASA (160-325 mg, chewed stat), clopidogrel (Plavix®), LMWH (enoxaparin), morphine, oxygen, NTG
    - ± reperfusion therapy with fibrinolytics (e.g. tPA, RPA, TNK, or SK) if within 12 h (ideally <30 min) or percutaneous intervention (cath lab) if <90 min
    - start β-blocker (e.g. metoprolol starting dose 25 mg PO q6h or bid, titrating to HR goal of 55-60 bpm)
- endocarditis: antibiotic choice is based on whether patient has a native or prosthetic heart valve as well as culture and sensitivity results
- GERD: antacids, H2 blockers, PPIs, patient education
- costochondritis: NSAIDs

**Treatment of Stable Ischemic Heart Disease**

- see Cardiology and Cardiac Surgery, C26

---

**Common Cold (Acute Rhinitis)**

- see Infectious Diseases, ID8 (Pneumonia and Influenza)

**Definition**

- viral URI with inflammation

**Epidemiology**

- most common diagnosis in family medicine, peaks in winter months
- incidence: adults = 2-4/yr, children = 6-10/yr
- organisms
  - mainly rhinoviruses (30-35% of all colds)
  - others: coronavirus, adenovirus, RSV, influenza, parainfluenza, coxsackie virus
- incubation: 1-5 d
- transmission: person-person contact via secretions on skin/objects and by aerosol droplets

**Risk Factors**

- psychological stress, excessive fatigue, allergic nasopharyngeal disorders, smoking, sick contacts

**Clinical Features**

- symptoms
  - local: nasal congestion, clear to mucopurulent secretions, sneezing, sore throat, conjunctivitis, cough
  - general: malaise, headache, myalgias, mild fever
- signs
  - boggy and erythematous nasal/oropharyngeal mucosa, enlarged lymph nodes
  - normal chest exam

</table>
• complications
  ▪ secondary bacterial infection: otitis media, sinusitis, bronchitis, pneumonia
  ▪ asthma/COPD exacerbation

Differential Diagnosis
• allergic rhinitis, pharyngitis, influenza, laryngitis, croup, sinusitis, bacterial infections

Management
• patient education
  ▪ symptoms peak at 1-3 d and usually subside within 1 wk
  ▪ cough may persist for days to weeks after other symptoms disappear
  ▪ no antibiotics indicated because of viral etiology
  ▪ secondary bacterial infection can present within 3-10 d after onset of cold symptoms
• prevention
  ▪ frequent hand washing, avoidance of hand to mucous membrane contact, use of surface disinfectant
  ▪ yearly influenza vaccination
• symptomatic relief
  ▪ rest, hydration, gargling warm salt water, steam, nasal irrigation (spray/pot)
  ▪ analgesics and antipyretics: acetaminophen, ASA (not in children because of risk of Reye’s syndrome)
  ▪ cough suppression: dextromethorphan or codeine if necessary (children under 6 yr of age should not use any cough/cold medications)
  ▪ decongestants, antihistamines
  ▪ zinc lozenge use may help to reduced the duration of cold symptoms
• patients with reactive airway disease will require increased use of bronchodilators and inhaled steroids

Contraception

Table 11. Methods of Contraception

<table>
<thead>
<tr>
<th>Methods</th>
<th>Advantages</th>
<th>Disadvantages</th>
</tr>
</thead>
<tbody>
<tr>
<td>Combined OCP (e.g. Alesse®, Tr-Conyle®)</td>
<td>99.9% effective with perfect use, 97-99% with typical use, cycle control, ↓ dysmenorrhea, ↓ menstrual flow, ↓ ovarian cancer, ↓ endometrial cancer, ↓ risk of fibroids, ↓ acne, ↓ hirsutism</td>
<td>Irregular bleeding, systemic hormonal side effects (breast tenderness, nausea, mood changes), no STD protection, slightly increased risk of venous thromboembolism (VTE), MI, stroke, decreased quantity of breast milk postpartum</td>
</tr>
<tr>
<td>Progestin Only Pill (e.g. Micronor®)</td>
<td>At least 95% effective with perfect use, no increased risk of VTE, MI, or stroke, suitable for postpartum</td>
<td>Hormonal side effects (see Combined OCP)</td>
</tr>
<tr>
<td>Transdermal Patch (e.g. Evra®)</td>
<td>Same as OCP, easy to use, changed weekly, 99% effective with correct use</td>
<td>Same as OCP, skin irritation</td>
</tr>
<tr>
<td>Nuvapril® (inserted by patient)</td>
<td>Same as OCP, easy to use (in for 3 wk, out for 1 wk), less systemic hormonal side effects, 99% effective with correct use</td>
<td>Same as OCP, vaginitis, some women may be uncomfortable with self-insertion</td>
</tr>
<tr>
<td>DMPA IM progesterone injection q12wk (e.g. DepoProvera®)</td>
<td>99.7% effective against pregnancy, infrequent dosing, ↓ menstrual flow or amenorrhea, ↓ risk of endometrial cancer</td>
<td>Irregular bleeding, delayed return of fertility, no STD protection, systemic hormonal side effects (most common is headache), weight gain, ↓ bone mineral density (check after 5 yr)</td>
</tr>
<tr>
<td>Male Condom</td>
<td>97% effective against pregnancy and STDs when used properly; when used properly WITH spermicide they are close to 99.9% effective, no Rx required</td>
<td>Latex allergy, irritation, only effective before the expiry date, must be applied properly, can only be used once</td>
</tr>
<tr>
<td>Diaphragm</td>
<td>92-96% effective with perfect use, non-hormonal, female-controlled method of contraception, ↓ risk of cervical cancer</td>
<td>Must be left in for 6 h after intercourse, must be used with spermicide, incomplete STD protection, latex allergy, must be fitted by health care worker, ↑ risk of UTI, risk of toxic shock syndrome</td>
</tr>
<tr>
<td>Sponge</td>
<td>One-size-fits-all barrier method, does not require fitting by MD, available in pharmacies, 90% effective without a condom, 98% effective with a condom</td>
<td>Relatively expensive, only ~60% effective in parous women, incomplete STD protection, risk of toxic shock syndrome</td>
</tr>
</tbody>
</table>

Concussion/Mild Traumatic Brain Injury

• see Neurosurgery, NS29, and Emergency Medicine, ER7
• a useful tool for the assessment of individuals and athletes with concussion is the Sport Concussion Assessment Tool, 3rd edition (SCAT3), Br J Sports Med 2013;47:259

Zinc for the Treatment of the Common Cold: A Systematic Review and Meta-Analysis of Randomized Controlled Trials

CMAJ 2012;184:E551-561
Study: Meta-analysis of 17 randomized control trials with a total of 2,121 participants.
Patients: All populations.
Intervention: Orally administered zinc vs. placebo or no treatment.
Results: Patients receiving zinc had a shorter duration of cold symptoms compared with those given placebo (mean difference -1.65 d). Zinc shortened the duration of symptoms in adults but no significant difference was seen in children. Adverse events such as nausea were more common in the zinc group (RR 1.640).

Echinacea for Preventing and Treating the Common Cold

Cochrane DB Syst Rev 2014;2:CD000530
This systematic review of 24 trials assessed the effect of Echinacea in preventing and treating common colds. Trials compared preparations containing Echinacea with placebo, no treatment, or an alternative common cold treatment.
Conclusions: Echinacea products have not been shown to provide benefits for treating colds, although, it is possible there is a weak benefit from some Echinacea products. Individual prophylaxis trials consistently show positive (if non-significant) trends, although potential effects are of questionable clinical relevance.
### Table 11. Methods of Contraception (continued)

<table>
<thead>
<tr>
<th>Method</th>
<th>Advantages</th>
<th>Disadvantages</th>
</tr>
</thead>
<tbody>
<tr>
<td>Intrauterine Device (IUD)</td>
<td>99% effective against pregnancy, effective for 5 yr, no daily regimen required, can be easily removed, ideal in post-partum women</td>
<td>No STD protection, † relative risk of PID in first mo, must be inserted by MD, risk of post-insertion vaso-vegal response, risk of uterine rupture is 0.6-1.6/1,000, 2-10% expulsion rate</td>
</tr>
<tr>
<td>Levonorgestrel (e.g., Mirena®)</td>
<td>Spotting, less systemic hormonal side effects than OCP</td>
<td>Hormonal side effects are possible with levonorgestrel IUD, but less than OCP (see combined OCP), expensive (~$400)</td>
</tr>
<tr>
<td>Copper IUD (e.g., Nova T®)</td>
<td>↓ risk of endometrial cancer, less expensive than Mirena (~$170)</td>
<td>Irregular bleeding or ↑ menstrual flow with copper IUD, 6-20% women discontinue use in first 5 yr because of pain or ↑ bleeding</td>
</tr>
<tr>
<td>Fertility Awareness/ Natural Family Planning (e.g., symptothermal method)</td>
<td>Effectiveness: 95-98% with perfect use, 75-88% with typical use, increased awareness of gynecological health, reasonable for couples for whom an unplanned pregnancy would be acceptable</td>
<td>High probability of failure if not used consistently and correctly, no STD protection</td>
</tr>
<tr>
<td>Lactational Amenorrhea</td>
<td>Can be effective in breastfeeding women if menses not returned, fully or nearly fully breastfeeding baby and baby is under 6 mo old</td>
<td>Not effective if infant receives any food supplementary to breastfeeding Must breastfeed regularly, even through the night (at least q6h) Most effective is breastfeeding q2-3h</td>
</tr>
</tbody>
</table>

### EMERGENCY CONTRACEPTION
- hormonal EC (Yuzpe® or Plan B®, usually 2 doses taken 12 h apart) or post-coital IUD insertion
- hormonal EC is effective if taken within 72 h of unprotected intercourse (reduces chance of pregnancy by 75-85%), most effective if taken within 24 h, does not affect an established pregnancy
- post-coital IUDs inserted within 5 d of unprotected intercourse are significantly more effective than hormonal EC (reduces chance of pregnancy by ~99%) |
- pregnancy test should be performed if no menstrual bleeding within 21 d of either treatment
- advance provision of hormonal EC increases the use of EC without decreasing the use of regular contraception
- pharmacists across Canada can dispense Plan B® OTC

### Cough

**History and Physical**
- duration (chronic - 8 wk), onset, frequency, quality (dry vs. productive), sputum characteristics, provoking/relieving factors, recent changes
- associated symptoms: fever, dyspnea, hemoptysis, wheezing, chest pain, orthopnea, PND, rhinitis, reflux, post-nasal drip
- constitutional symptoms: fever, chills, fatigue, night sweats
- risk factors: smoking, occupation, exposure, family history of lung CA or other CA, TB status, recent travel
- medications (e.g. ACEI, β-blockers), allergies
- PMH: lung (asthma, COPD, CF), heart (CHF, MI, arrhythmias), chronic illness, GI (reflux)  
- vitals including O₂ saturation, respiratory exam, HEENT and precordial exam

**Investigations**
- guided by findings on history and physical
  - consider throat swab, CXR, PFTs, upper GI series, sputum culture test for acid-fast bacilli (if TB is suspected)

### Dementia (Major Neurocognitive Disorder)

- see Psychiatry, PS17

**Epidemiology**
- 10% in patients over the age of 65, 25% in patients over the age of 85, 50% in patients over the age of 90
- prevalence increases with age, Down syndrome, and head trauma
- differential diagnosis: Alzheimer’s dementia, vascular dementia, Lewy-Body dementia, frontotemporal dementia

**Investigations**
- history, physical exam, MMSE, MOCA (best screening test), dementia quick screen (see sidebar)
- investigations are completed to exclude reversible causes of dementia and should be selected based on the clinical circumstances
- CBC, liver enzymes, TSH, renal function tests, serum electrolytes, serum calcium, serum glucose, vitamin B₁₂, folate, VDRL, HIV, head CT
Management

- Treat and prevent reversible causes
- Provide orientation cues (e.g., calendars, clocks) and optimize vision and hearing
- Family education, counseling, and support (respite programs, group homes)
- Pharmacologic therapy: NMDA receptor antagonists and cholinesterase inhibitors slow rate of cognitive decline; low-dose neuroleptics and antidepressants can be used to treat behavioral and emotional symptoms
- 20% of patients develop clinical depression, most commonly seen in vascular dementia

Depression

- See Psychiatry, PS6

Etiology

- Often presents as non-specific complaints (e.g., sleep disturbance, chronic fatigue, pain)
- Depression is a clinical diagnosis and tests are done in order to rule out other causes of symptoms
- 2/3 of depressed persons may not receive appropriate treatment for their depression
- Identification and early treatment improve outcomes

Screening Questions

- The AAFP recommends screening adults for depression when staff-assisted depression care supports are available (Grade B)
- “Staff-assisted depression care supports” refers to clinical staff that assist the primary care physician in providing direct depression care and/or coordination, case management, or mental health treatment
- If staff-assisted depression care supports are not available, the AAFP recommends against routine screening of adults (Grade C) (note: there may be considerations that support screening for depression in an individual patient)
  - “Are you depressed?” (high specificity and sensitivity)
  - “Have you lost interest or pleasure in the things you usually like to do?” (anhedonia)
  - “Do you have problems sleeping?”
- For geriatric population, use the Geriatric Depression Scale (GDS) short form for screening

Assessment

- Risk factors: see Psychiatry, PS7
- Personal or family history of depression
- Medications and potential substance abuse problems
- High risk suicidality/homicidality
  - Fill out Form 1 (in Ontario): application by physician to hospitalize a patient against his/her will for psychiatric assessment (up to 72 h)
  - Functional impairment (e.g., work, relationships)
- At least 5 out of 9 criteria including at least one of anhedonia or depressed mood ≥2 wk for actual diagnosis to be met (see sidebar)
- Validated depression rating scales: Beck’s depression inventory, Zung’s self-rating depression scale, Children’s depression inventory, Geriatric Depression Scale, Personal Health Questionnaire Depression Scale (PHQ-9)
- Routine medical workup (physical exam, CBC, TSH, ferritin, folate, B12, electrolytes, urinalysis, glucose, etc.)

Treatment

- Goal: full remission of symptoms and return to baseline psychosocial function
- Phases of treatment
  - Acute phase (8-12 wk): relieve symptoms and improve quality of life
  - Maintenance phase (6-12 mo after symptom resolution): prevent relapse/recurrence, must stress importance of continuing medication treatment for full duration to patients
  - Treatment can consist of pharmacotherapy alone or psychotherapy alone
  - Combination of antidepressant drug therapy and psychotherapy results in synergistic effects
  - Treatment of youth (age 10-21)
    - For mild depression, a period of active support and monitoring before initiating treatment is recommended
    - Fluoxetine is first line among SSRIs (most evidence)
    - Monitor closely for adverse effects such as suicidal ideation and behavior
    - Psychotherapy
      - CBT or interpersonal therapy (IPT) alone can be used for mild depression
      - Psychotherapy plus medication is recommended for moderate to severe depression
      - Treatment should continue for at least 6 mo
      - Ongoing management should include assessment in key domains (school, home, social setting)
  - Reassessment and referral recommended if no improvement after 6-8 wsks of treatment
  - For adolescents with moderate/severe depression and coexisting psychosis and/or substance abuse, consider referral

Dementia Quick Screen

- 3 simple tests, takes about 2 min
- Use when suspect mild cognitive impairment or when patient is at high risk
- Screen involves:
  1. 3 word recall (normal = recalls 2-3 words)
  2. Naming animals in 1 min (normal = > 12 in one min)
  3. Clock Drawing – including numbers and hands so time shows 10 min past 11 (normal = correct number/hand placing, or only minor spacing problems)
- Interpretation: If all 3 results within normal range, cognitive impairment unlikely.
- If any results abnormal, possible cognitive impairment, further evaluation necessary.

Must Ask About/Rule Out

- Suicidal/homicidal ideation
- Psychosis
- Substance use/abuse/withdrawal
- Anxiety
- Bipolar/manic/hypomanic episodes
- Bereavement
- Intimate partner violence
- Post-partum depression
- Organic cause

Differential Diagnosis

- Other psychiatric disorders (e.g., anxiety, personality, bipolar, adjustment disorder, schizophrenia, seasonal affective disorder, substance abuse/withdrawal)
- Cancer (50% of patients with tumors, especially of brain, lung, and pancreas, develop symptoms of depression before the diagnosis of cancer is made)
- Chronic fatigue syndrome
- Early dementia
- Endocrine (e.g., hyper/hypothyroidism, DM, adrenal disorders)
- Infections (mononucleosis)
- Liver failure, renal failure
- Medication side effects (β-blockers, benzodiazepines, glucocorticoids, interferon)
- Menopause
- Neurological (Parkinson’s, MS)
- Vitamin deficiency (pemphigus, pellagra)
Diabetes Mellitus

- see Endocrinology: E6

Epidemiology
- incidence of type 2 DM is rising dramatically as a result of an aging population, rising rates of obesity, and sedentary lifestyles
- leading cause of new-onset blindness and renal dysfunction
- adults with DM are twice as likely to die prematurely, compared to persons without DM

Risk Factors
- type 1 DM
  - personal or family history of autoimmune disease
- type 2 DM
  - first degree relative with DM
  - age ≥40
  - obesity (especially abdominal), HTN, hyperlipidemia, CAD, vascular disease
  - prior GDM, macrosomia baby (>8 lb 13 oz)
  - PCOS
  - history of IGT or IFG
  - presence of complications associated with DM
  - presence of associated diseases: PCOS, acanthosis nigricans, psychiatric disorders, HIV
  - medications: glucocorticoids, atypical antipsychotics, HAART
- both
  - member of a high risk population (e.g. Aboriginal, Hispanic, Asian, or African descent)

Diagnosis
- persistent hyperglycemia is the hallmark of all forms of DM

</table>

Fasting or Preprandial BG
- Ideal: 72-126 mg/dL
- Suboptimal: 128-180 mg/dL; action may be required
- Inadequate: >180 mg/dL; action required

HbA1c
- ≤7% or ≤6.5% in some type 2 DM patients at risk for nephropathy
- Suboptimal: 7-8.4%
- Inadequate: >8.4%

2 h Postprandial BG
- 90-180 mg/dL if HbA1c target met
- 90-144 mg/dL if HbA1c target not met

Blood Pressure
- <130/80 in adults (DM and HTN guidelines)

Lipids
- LDL <36 mg/dL
- Triglycerides <27 mg/dL
- Total cholesterol/HDL ratio <72 mg/dL

Dietary Advice for Treatment of Type 2 DM in Adults
- Cochrane DB Syst Rev 2009;2:CDO005270
- A meta-analysis, using 18 studies comprising 5,168 patients, investigated the effectiveness of diet control, physical activity, behavioral weight programs, and weight control interventions in adults with pre-DM. The analysis was limited by heterogeneous patient populations, but when compared with usual care, weight loss was 2.8 kg and BMI decrease was 1.3 kg/m² at 1 yr. Modest but non-significant improvements in glycemic control, BP and blood lipid concentrations were noted. Studies with a follow-up of 3-6 yr showed a significant decrease in DM onset when compared with controls.

Dietary Advice for Treatment of Type 2 DM in Adults
- Cochrane DB Syst Rev 2007;3:CDO04097
- A meta-analysis, using 36 articles reporting a total of 18 trials following 7,481 participants, showed that there is no high quality data on the efficacy of dietary treatment of type 2 DM. After 6 and 12 mo, adoption of exercise improved HbA1c.

</tbody>
</table>

**Management**
- Nutritional and physical education
- Consider referral to DM education program if available
- Monitoring BG: explain methods and frequency
- Medication counseling: oral hypoglycemics and/or insulin, method of administration, dosage adjustments
- Pneumococcal vaccination
- Ophthalmology consult
  - type 1 DM within 5 yr
  - type 2 DM at diagnosis
  - Assess progress towards long-term complications
  - Adjust treatment plan if necessary
  - Calibrate home glucose monitor
  - Arrange ophthalmology follow-up annually for type 1 DM and q2yr for type 2 DM
  - Influenza vaccination annually

**Nonpharmacologic Management**
- **diet**
  - all diabetics should see a registered dietician
  - can reduce HbA1c by 1-2%
  - strive to attain healthy body weight
  - decrease combined saturated fats and trans-fatty acids to <10% of calories
  - avoid simple sugars, encourage complex carbohydrates, choose low glycemic-index foods
- **physical activity and exercise**
  - at least 150 min of aerobic exercise per wk, plus 2 sessions per wk of resistance exercise is recommended
  - encourage 30-45 min of moderate exercise 4-7 d/wk
  - promote cardiovascular fitness: increases insulin sensitivity, lowers BP, and improves lipid profile
  - if insulin treated, may require alterations of diet, insulin regimen, injection sites, and self-monitoring

**Self-Monitoring of Blood Glucose**
- type 1 DM: 3 or more self-tests/d is associated with a 1% reduction in HbA1c
- type 2 DM: recommendations vary based on treatment regimen (e.g., insulin dependent requires more frequent monitoring - refer to 2014 American Practice Guidelines)
- if FBG >252 mg/dL, perform ketone testing to rule out DKA
- if bedtime level is <126 mg/dL, have bedtime snack to reduce risk of nocturnal hypoglycemia

![Figure 4. Types of insulin preparation](image-url)
Figure 5. Management of hyperglycemia in type 2 diabetes

**Hypoglycemic Agents (Type 2 DM)**
- oral
  - biguanide: metformin (Glucophage™)
  - thiazolidinedione: troglitazone (Rezulin™), rosiglitazone (Avandia™), pioglitazone (Actos™)
  - α-glucosidase inhibitor: acarbose (Precose™)
  - nonsulfonylureas: nateglinide (Starlix™), repaglinide (GlucoNorm™)
  - sulfonylureas: glyburide (DiaBeta™), glimepiride (Amaryl™), gliclazide (Diamicon™)
  - DPP-4 inhibitor: sitagliptin (Januvia™)
- injectable
  - GLP-1 analogue: liraglutide (Victoza™)

**Other Medications Used in DM**
- ACEI for
  - all hypertensive diabetics
  - elevated microalbuminuria (30-300 mg albumin in urine in 24 h)
  - overt nephropathy (>300 mg albumin in urine in 24 h)
- ARBs are second line for these conditions
• ASA 81 mg OD for secondary prevention of CVD (should not be used for primary prevention of CVD in people with DM)
• statins
  ▪ as required to attain target lipid profile (LDL-C <36 mg/dL)

## Diarrhea

• see Gastroenterology, G15, and Infectious Diseases, ID11

### Definition

• passage of 3 or more loose or liquid stools in a day or more frequently than is normal for the individual (WHO definition)
• can be acute (<14 d duration) or chronic (>14 d duration)

### Etiology and Clinical Features

- acute diarrhea
  ▪ majority of cases are self-limiting
  ▪ most commonly caused by viral infection (e.g. rotavirus, norovirus)
  ▪ fever and bloody stools increase probability of bacterial infection
  ▪ consider *C. difficile* infection if recent hospitalization, recent antibiotic use (e.g. broad spectrum antibiotics, fluoroquinolones, clindamycin), chronic use of PPIs, age >65, immunosuppression

- chronic diarrhea
  ▪ most commonly of non-infectious etiology
  ▪ common causes include drugs (e.g. laxatives, antibiotics), infection (e.g. bacteria, parasites), inflammation (e.g. IBD, diverticulitis), neoplasia (e.g. colon cancer), malabsorption (e.g. celiac disease), maldigestion (e.g. lactose intolerance), and idiopathic

### Treatment

- acute diarrhea: ensure adequate hydration, treat underlying cause (e.g. antibiotics for bacterial infection)
- chronic diarrhea: nonspecific treatment often required before workup is complete
  ▪ oral rehydration solution (if needed): offset electrolyte imbalances
  ▪ lifestyle modification (dietary changes, exercise)
  ▪ fiber (e.g. psyllium): commonly used as adjunctive treatment
  ▪ antidiarrheal opiates (e.g. loperamide): most effective nonspecific treatment
  ▪ should be used on a scheduled basis before meals rather than prn

## Dizziness

• see Otolaryngology, OT6

### Epidemiology

• 70% see general practitioners initially; 4% referred to specialists
• frequency proportional to age; commonest complaint of ambulatory patients age >75
Differential Diagnosis

**Vertigo (vestibular)**
- Objective (external world seems to revolve around individual) or subjective (individual revolves in space)

- **Central (15%)**
  - Brainstem
  - Cerebellar

- **Peripheral (85%)**
  - Inner ear
  - Vestibular nerve

- Psychogenic Diagnosis of exclusion

- **Vascular**
  - BPPV
  - Basilar migraine
  - TIAs
  - Orthostatic hypotension
  - Stokes-Adams syndrome
  - Anhydrotic
  - CHF

- **Ocular**
  - Decreased visual acuity

**Nonvertiginous (nonvestibular)**
- Feeling “light-headed,” “giddy,” “blazed,” “mentally confused,” or “disoriented”

- **Central (15%)**
  - Brainstem
  - Cerebellar

- **Peripheral (85%)**
  - Inner ear
  - Vestibular nerve

**History**
- Clarify type of dizziness: vertigo, pre-syncpe, disequilibrium, light-headedness
- Duration (seconds, minutes, hours, days, weeks, or persistent)
- Exacerbations
  - Worse with head movement or eye closure (vestibular)
  - No change with head movement and eye closure (nonvestibular)
  - Worse with exercise (cardiac/pulmonary causes)
- Associated symptoms
  - Neurologic (central)
    - Transient diplopia, dysphagia, dysarthria, ataxia (TIA, VBI, migraine)
    - Persistent headache, alterations in level of consciousness, sensory and/or motor deficits (CNS)
  - Audiologic (peripheral)
    - Hearing loss, tinnitus, otalgia, aural fullness
  - Others
    - N/V (peripheral vestibular disorders)
    - SOB, palpitations (hyperventilation, cardiac problem)
- General medical history
  - HTN, DM, heart disease, fainting spells, cerebrovascular disease, migraines
  - Otoxic drugs: aminoglycosides (gentamicin, streptomycin, tobramycin), erythromycin, ASA, antimalarials
  - Hypotension (secondary to diuresis): furosemide, caffeine, alcohol

**Physical Exam/Investigations**
- Syncope
  - Cardiac (orthostatic changes in vials), peripheral vascular, and neurologic exams
  - Blood work, ECG, 24 h Holter, treadmill stress test, loop ECG, tilt table testing, carotid and vertebral doppler, EEG
- Vertiginous
  - ENT and neurologic exams
  - Dix-Hallpike, consider audiometry and MRI if indicated
- Non-syncope, non-vertiginous
  - Cardiac and neurologic exams
  - 3-min hyperventilation trial (patient is coached to hyperventilate until patient becomes dizzy to identify if symptoms are reproducible and confirm that hyperventilation is the etiology of the symptoms), ECG, EEG

**Treatment**
- Guided by history, physical exam, and investigations
- Include education, lifestyle modification, physical maneuvers (e.g. Epley for BPPV), symptomatic management (e.g. antiemetics), pharmacotherapy, and surgery
- Refer when significant central disease is suspected, when vertigo of peripheral origin is persistent (lasting >2-4 wk), or atypical presentation

---

**DDx of Vertigo**

- **BPPV =** benign paroxysmal positional vertigo
- **TIA =** transient ischemic attack
- **VBI =** vertebral basilar insufficiency

**DDx of Vertigo**

- **Onset** sudden, sudden, gradual, insidious
- **Duration** seconds, days, minutes, hours, chronic
- **Hearing**
  - Loss
  - **Tinnitus**
  - **Neuro Sx**

**Figure 6. Differential diagnosis of dizziness**

**Dix-Hallpike Test**
- Have the patient seated with legs extended and head at 45° rotation
- Rapidly shift patient to supine position with head fully supported in slight extension (for 45 s)
- Observe for rotatory nystagmus and ask about sensation of vertigo

**Vertigo**
- Objective (external world seems to revolve around individual) or subjective (individual revolves in space)

**Nonvertiginous**
- Feeling “light-headed,” “giddy,” “blazed,” “mentally confused,” or “disoriented”

**Etiology**

- Central (15%)
  - Brainstem
  - Cerebellar

- Peripheral (85%)
  - Inner ear
  - Vestibular nerve

- Psychogenic Diagnosis of exclusion

- Vascular
  - BPPV
  - Basilar migraine
  - TIAs
  - Orthostatic hypotension
  - Stokes-Adams syndrome
  - Anhydrotic
  - CHF

- Ocular
  - Decreased visual acuity
Domestic Violence/Elder Abuse

INTIMATE PARTNER VIOLENCE

Definition
- includes physical, sexual, emotional, psychological, and financial abuse
  (see Emergency Medicine, ER29)

Epidemiology
- lifetime prevalence of intimate partner violence against women is between 25-30%
- women who experience abuse have increased rates of injury, death, and health consequences including 50-70% increase in gynecological, central nervous system, stress-related problems
- occurs in all socioeconomic, educational, and cultural groups with increased incidence in pregnancy, disabled women, and 18-24 age group
- 25-50% chance of child abuse or neglect in families where partner abuse occurs
- physician recognition rates as low as 5%

Presentation
- multiple visits with vague, ill-defined complaints such as: headaches, gastrointestinal symptoms, insomnia, chronic pain, hyperventilation
- may also present with injuries inconsistent with history

Management
- screen ALL patients
  - always have a high index of suspicion
  - asking about abuse is the strongest predictor of disclosure
  - several screening tools (see sidebar) exist to identify victims of partner violence
  - make sure to determine the victim's level of immediate and long-term danger and ask if there are weapons in the house
- ensure patient safety
  - victim most at risk for homicide when attempting to leave home or following separation
  - provide community resources
  - safety planning includes ensuring that there is access to an exit in the home, establishing a safe place to go and having money, clothes, keys, medications, important documents, and other emergency items prepared should the patient need to leave quickly
  - shelter or helpline number with legal advocacy and counseling services
  - involve social workers or domestic violence advocates
- appointment for follow-up to assess whether condition is better or worse
- reassure patient she/he is not to blame and that the assault is a crime
  - goal is to convey the message that "As your doctor, I am concerned for your safety" and "Your partner has a problem that he/she needs help with" and "I want to help you"
  - reporting suspected or known child abuse is mandatory (see Emergency Medicine, ER59)
- DOCUMENT all evidence of abuse-related visits for medico-legal purposes

ELDER ABUSE

- see Geriatric Medicine, GM4

Dyspepsia

- see Gastroenterology, G10

Definition and Clinical Features
- defined as epigastric pain or discomfort
- can be associated with fullness, belching, bloating, heartburn, food intolerance, N/V

Epidemiology
- annual incidence 1-2%, prevalence 20-40%

Etiology
- common: functional, PUD, GERD, gastritis
- others: cholelithiasis, irritable bowel syndrome, esophageal or gastric cancer, pancreatitis, pancreatic cancer, Zollinger-Ellison syndrome, and abdominal angina

History
- symptoms may not be useful in finding cause
- association with food, anorexia, N/V alcohol, NSAID use
Investigations and Management
- lifestyle modifications: dietary changes, smaller and more frequent meals, avoid supine position right after meals, decreased EtOH consumption, smoking cessation
- empiric therapy: H₂ receptor blockers, PPIs for short periods of time (8 wk with taper)
- testing for H. pylori: serology, urea breath test
- upper endoscopy (preferred), upper GI series

Dyspnea
- see Respiratory, R3 and Emergency Medicine, ER27

History and Physical Exam
- history
  - cough, sputum, hemoptysis, wheezing, chest pain, palpitations, dizziness, edema
  - asthma, allergy, eczema, ASA/NSAID sensitivity, nasal polyps
  - constitutional symptoms
  - smoking, recreational drugs, medications
  - occupational exposure, environmental exposure (e.g. pets, allergens, smoke)
  - travel and birth place
  - FHx of atopy
- physical exam: vitals, respiratory, precordial, HEENT, signs of anemia/liver failure/heart failure

Investigations
- CXR, ECG
- PFTs, ABG acutely if indicated

Management
- ABCs: send to ED if in severe respiratory distress
- depends on cause

Dysuria
- see Urology, U10

Definition
- the sensation of pain, burning, or discomfort on urination

Epidemiology
- in adulthood, more common in women than men
- approximately 25% of women report one episode of acute dysuria per yr
- most common in women age 25-54 and in those who are sexually active
- in men, dysuria becomes more prevalent with increasing age

Etiology
- infectious
  - most common cause
    - presents as cystitis, urethritis, pyelonephritis, vaginitis, cervicitis, epididymo-orchitis, or prostatitis
- non-infectious
  - hormonal conditions (hypoestrogenism), obstruction (BPH, urethral strictures), allergic reactions, radiation, drugs/chemicals, foreign bodies, trauma, neoplasm, kidney stones, inflammatory diseases, endometriosis, psychogenic

Table 16. Etiology, Signs and Symptoms of Common Causes of Dysuria

<td>E. coli, S. saprophyticus, Proteus mirabilis, Enterobacter, Klebsiella, Pseudomonas</td>
<td>Internal dysuria, fever, chills, flank pain radiating to groin, CVA tenderness, N/V</td>
</tr>
</tbody>
</table>
Investigations
- no investigations necessary when history and physical consistent with uncomplicated UTI – treat empirically (urinalysis can be performed when indicated by dipstick or microscopy)
- urinalysis/dipstick: positive for nitrites and leukocytes
- urine R&M: pyuria, bacteriuria, hematuria
- urine C&S
- CBC and differential if suspecting pyelonephritis
- if vaginal/urethral discharge present: wet mount, Gram stain, KOH test, vaginal pH, culture for yeast and trichomomas, endocervical/urethral swab or urine PCR for N. gonorrhoeae and C. trachomatis
- radiologic studies and other diagnostic tests if atypical presentation
- see Pediatrics, P64 for UTI in children

Management
- see Antimicrobial Quick Reference, FM52 for treatment
- UTI/cystitis
  - pregnant women with bacteriuria (2-7%) must be treated even if asymptomatic, due to risk of preterm labor; need to follow with monthly urine cultures and retreat if still infected
  - patients with recurrent UTIs (>3/yr) should be considered for prophylactic antibiotics
  - if complicated UTI, patients require longer courses of broader spectrum antibiotics
- urethritis
  - when swab or PCR is positive for chlamydia or gonorrhea must report to Public Health
  - all patients should return 4-7 d after completion of therapy for clinical evaluation

Epistaxis
- see Otolaryngology, OT27

Erectile Dysfunction
- see Urology, U30

Definition
- consistent or recurrent inability to attain and/or maintain penile erection sufficient for sexual performance of ≥3 mo duration

Epidemiology
- ~20% of men age 40; ~50% of men age 70

Etiology
- organic: vascular (90%) (arterial insufficiency, atherosclerosis), endocrine (low testosterone, DM), anatomic (structural abnormality, e.g. Peyronie’s), neurologic (post-operative, DM), medications (clonidine, antihypertensives, psychotropics)
- psychogenic (10%)

Walsh: Campbell’s Urology, 8th ed. Table 46-4
History

- comprehensive sexual, medical, and psychosocial history
- time course
  - last satisfactory erection
  - gradual or sudden onset
  - attempts at sexual activity
- quantify
  - presence of morning or night time erections
  - stiffness (scale of 1-10)
  - ability to initiate and maintain an erection with sexual stimulation
  - erection stiffness during sex (scale of 1-10)
- qualify
  - partner or situation specific
  - loss of erection before penetration or climax
  - degree of concentration required to maintain an erection
  - percentage of sexual attempts satisfactory to patient and/or his partner
  - significant bends in penis or pain with erection
  - difficulty with specific positions
  - impact on quality of life and relationship

Investigations

- hypothalamic-pituitary-gonadal axis evaluation: testosterone (free + total), prolactin, LH
- risk factor evaluation: fasting glucose, HbA1c, lipid profile
- others: TSH, CBC, urinalysis
- specialized testing
  - psychological and/or psychiatric consultation
  - in-depth psychosexual and relationship evaluation
  - nocturnal penile tumescence and rigidity (NPTR) assessment
  - vascular diagnostics (e.g. doppler studies, angiography)

Management

</tbody>
</table>

Common causes are in **bold**

Investigations

- psychosocial causes are common, so usually minimal investigation is warranted
- physical causes of fatigue usually have associated symptoms/signs that can be elicited from a focused history and physical exam
- investigations should be guided by history and physical exam and may include
  - CBC and differential, electrolytes, BUN, Cr, ESR, glucose, TSH, ferritin, vit B12, serum protein electrophoresis, Bence-Jones protein, albumin, AST, ALT, ALP, bilirubin, calcium, phosphate, ANA, β-hCG
  - urinalysis, CXR, ECG
  - additional tests: serologies (Lyme disease, hepatitis B and C screen, HIV, ANA) and Mantoux skin tests

Treatment

- treat underlying cause
- if etiology cannot be identified (1/3 of patients)
  - reassurance and follow-up, especially with fatigue of psychogenic etiology
  - quick follow-up for reassurance
  - supportive counseling, behavioral, or group therapy
  - encourage patient to stay physically active to maximize function
  - review all medications, OTC, and herbal remedies for drug-drug interactions and side effects
  - prognosis: after 1 yr, 40% are no longer fatigued

**CHRONIC FATIGUE SYNDROME**

**Definition (CDC 2006)** – must meet both criteria
1. new or definite onset of unexplained, clinically evaluated, persistent or relapsing chronic fatigue, not relieved by rest, which results in occupational, educational, social, or personal dysfunction
2. concurrent presence of at least 4 of the following symptoms for a minimum of 6 mo
   - impairment of short-term memory or concentration, severe enough to cause significant decline in function
   - sore throat
   - tender cervical or axillary lymph nodes
   - muscle pain
   - multi-joint pain with no swelling or redness
   - new headache
   - unrefreshing sleep
   - post-exertion malaise lasting >24 h
- exclusion criteria: medical conditions that may explain the fatigue, certain psychiatric disorders (depression with psychotic or melancholic features, schizophrenia, eating disorders), substance abuse, severe obesity (BMI >45)

**Exercise Therapy for Chronic Fatigue**

*Cochrane Depression, Anxiety, and Neurosis Group*

*Cochrane DB Syst Rev 2004; Issue 3*

**Purpose:** To determine the effectiveness of exercise therapy for Chronic Fatigue Syndrome (CFS).

**Methods:** Systematic review of 5 RCTs with 336 patients of all ages with a clinical diagnosis of CFS.

**Results:** At 12 wk, patients undergoing exercise therapy were less fatigued than controls (SMD -0.77; 95% CI -1.26 to -0.28). Physical functioning was also significantly improved, but there were more dropouts with exercise therapy. Compared with fluoxetine, patients receiving exercise therapy were less fatigued (WMD -1.24; 95% CI -5.31-2.83). Patients receiving combination therapy with exercise therapy and either fluoxetine or patient education, did better than those on monotherapy.

**Conclusions:** Patients may benefit from exercise therapy. Combination therapy with either fluoxetine or education may offer additional benefit. Further high quality trials are needed.
Epidemiology
- F>>M, Caucasians > other groups, majority in their 30s
- found in <5% of patients presenting with fatigue

Etiology
- unknown, likely multifactorial
- may include infectious agents, immunological factors, neurohormonal factors, and/or nutritional deficiency

Investigations
- no specific diagnostic laboratory tests

Treatment
- promote sleep hygiene
- provide support and reassurance that most patients improve over time
- non-pharmacological
  - regular physical activity, optimal diet, psychotherapy (e.g. CBT), family therapy, support groups
- pharmacological
  - to relieve symptoms: e.g. antidepressants, anxiolytics, NSAIDs, antimicrobials, antiallergy therapy, antihypotensive therapy

Fever
- see Pediatrics, P54, for fever in pediatric population

Definition
- temperature >100.4°F (38 °C)
- fever in children under 2 must be a rectal temperature for accuracy
- TM not accurate for measurement until child is over the age of 5

History
- fever
  - peak temperature, thermometer, route, duration
  - time of day
  - response to antipyretics
- systemic symptoms
  - weight loss, fatigue, rash, arthralgia, night sweats
- symptoms of possible source
  - UTI/pyelonephritis: dysuria, foul-smelling urine, incontinence, frequency, hematuria, flank pain
  - pneumonia: cough, pleuritic chest pain
  - URTI: cough, coryza, ear pain
  - meningitis: headache, confusion, stiff neck, rash
  - osteomyelitis: bone pain
  - skin: purulent discharge
  - PID: discharge, dyspareunia, lower abdominal pain
  - gastroenteritis: abdominal pain, diarrhea, blood per rectum, vomit
  - medications
  - PE/DVT: swollen legs, pain in calf, SOB, pleuritic chest pain
  - history of cancer/family history of cancer
- infectious contacts
  - travel history, camping, day care, contact with TB, foodborne, animals

Possible Investigations
- CBC and differential, blood culture, urine culture, urinalysis
- stool O&P, Gram stain, culture
- CXR, Mantoux skin test, sputum culture
- LP
Management
• increase fluid intake
• general: sponge bath, light clothing
• acetaminophen/ibuprofen as needed
• treat underlying cause

Headache

• see Neurology, N43

</tbody>
</table>

Secondary Headaches

• caused by underlying organic disease
• account for <10% of all headaches, may be life-threatening
• etiology
  ▪ aneurysm
  ▪ medication overuse headache
  ▪ space-occupying lesion
  ▪ systemic infection (meningitis, encephalitis)
  ▪ stroke
  ▪ subarachnoid hemorrhage
  ▪ systemic disorders (thyroid disease, HTN, pheochromocytoma, etc.)
  ▪ temporal arteritis
  ▪ traumatic head injuries
  ▪ TMJ or C-spine pathology
  ▪ serious ophthalmological and otolaryngological causes of headache
• treatment
  ▪ based on underlying disorder
  ▪ analgesics may provide symptomatic relief

Investigations

• indicated only when red flags are present and may include:
  ▪ CBC for suspected systemic or intracranial infection
  ▪ ESR for suspected temporal arteritis
  ▪ neuroimaging (CT or MRI) to rule out intracranial pathology
  ▪ CSF analysis for suspected intracranial hemorrhage, infection

Migraine Screen

POUND
P: pulsatile quality
O: over 4-72 h
U: unilateral
N/V: disabling intensity
D: if ≥4 present then a diagnosis is likely (+ LR = 24)

Acupuncture for Migraine Prophylaxis

Cochrane DB Syst Rev 2009;4:CD001218

Study Meta-analysis of 22 RCTs.

Population: 4,419 participants with diagnosed migraine.

Intervention: Preventive treatment with acupuncture, sham acupuncture, no prophylactic treatment/routine care only, other interventions.

Main Outcome Measure: Proportion of responders in 3-4 mo.

Other Outcomes: Frequency of migraine attacks, number of migraine days, headache frequency.

Results: Patients receiving acupuncture had higher response rates and fewer headaches after 3-4 mo than those with no prophylactic treatment or routine care only. There was no statistically significant difference between “true” vs. “sham” acupuncture.

Conclusion: Acupuncture is a viable prophylactic treatment option for migraine attacks. Selecting specific points for acupuncture is not as important as believed by practitioners.
Hearing Impairment

- see Otolaryngology: OT9

Definition
- hearing impairment: a raised hearing threshold measured as decibels of hearing loss relative to the normal population at specific frequencies
- hearing disability: hearing impairment that interferes with performing daily tasks

Epidemiology
- prevalence increases with age (6% of 35-44 yr old, 43% of 65-84 yr old)
- 90% of age-related hearing loss (presbycusis) is sensorineural
- hearing loss detectable by audiology is present in greater than 1/3 of people over 65
- associated with significant physical, functional, and mental health consequences

Classification
- conductive (external sound does not reach the middle ear)
- sensorineural involving the inner ear, cochlea, or auditory nerve
- mixed

Assessment
- infants
  - universal newborn hearing screening program
- elderly
  - presbycusis is characterized by the progressive, symmetric loss of high-frequency hearing
  - tinnitus, vertigo, and disequilibrium may be present
  - can cause low self-esteem, isolation, and depression
- whispered-voice test
  - whisper 6 test words 6 in to 2 ft away from the patient’s ear out of the visual field, ask patient to repeat the words (with non-test ear distraction)
- tuning fork test (to distinguish conductive from sensorineural hearing loss)
  - Rinne and Weber (not for general screening)
- formal audiologic assessment
  - pure tone, air, and bone conduction testing
  - speech audiometry
  - impedance audiometry

Management
- counsel about noise control and hearing protection programs (Grade A evidence)
- investigations in patients with unexplained sensorineural hearing loss
  - blood sugar, CBC+ differential, TSH, syphilis testing
- referral
  - refer patients with hearing loss for a complete audiological examination
  - unclear etiology of hearing loss: referral to ENT
  - sudden hearing loss: urgent referral as treatment success is related to early treatment
- patients with progressive asymmetric sensorineural hearing loss should have an MRI/CT scan to exclude vestibular schwannoma (acoustic neuroma)
- hearing amplification (e.g. hearing aids), assistive listening devices, and cochlear implants can dramatically improve quality of life

Hypertension

Hypertension Guidelines are reviewed and updated annually.
For up to date recommendations, please see www.hypertension.ca/chept

Epidemiology
- about 1 in 3 U.S. adults (67 million people) have HTN, only half of these individuals are able to control their condition
- 3rd leading risk factor associated with death

Definition
- HTN
  - BP ≥140/90 mmHg, unless DM (≥130/80 mmHg), or age ≥80 yr (≥150/90 mmHg)
- isolated systolic HTN
  - sBP ≥140 and dBP <90
  - associated with progressive reduction in vascular compliance
  - usually begins in 5th decade
• hypertensive urgency
  ▪ sBP >210 or dBP >120 with minimal or no target-organ damage
• hypertensive emergency
  ▪ severe HTN + acute target-organ damage
  ▪ accelerated HTN
    • significant recent increase in BP over previous hypertensive levels associated with evidence of vascular damage on fundoscopy, but without papilledema
  ▪ malignant HTN
    • sufficient elevation in BP to cause papilledema and other manifestations of vascular damage (retinal hemorrhages, bulging discs, mental status changes, increasing creatinine)

Etiology
• essential (primary) HTN (>90%)
  ▪ undetermined cause
• secondary HTN (10%)
• watch for labile, “white coat” HTN (office-induced elevated BP)

Predisposing Factors
• family history
• obesity (especially abdominal)
• alcohol consumption
• stress
• sedentary lifestyle
• smoking
  ▪ male
  ▪ age >30
  ▪ excessive salt intake/fatty diet
  ▪ African American ancestry
  ▪ dyslipidemia

Investigations
• for all patients with HTN
  ▪ electrolytes, Cr, fasting glucose and/or HbA1c, lipid profile, 12-lead ECG, urinalysis
  ▪ self-measurement of BP at home is encouraged
• for specific patient subgroups
  ▪ DM or CKD: urinary protein excretion
  ▪ if suspected renovascular HTN: renal ultrasound, captopril renal scan (if GFR >60 mL/min), MRA/CTA (if normal renal function)
  ▪ if suspected endocrine cause: plasma aldosterone, plasma renin
    • measured from morning samples taken from patients in sitting position after resting 15 min
    • discontinue aldosterone antagonists, ARBs, β-blockers, and clonidine prior to testing
  ▪ if suspected pheochromocytoma: 24 h urine for metanephrines and creatinine
  ▪ echocardiography for left ventricular dysfunction assessment if indicated
**Diagnosis**

**The Expedited Assessment and Diagnosis of Patients with Hypertension**

Focus on Validated Technologies for Blood Pressure Assessment

- Elevated Out of the Office BP Measurement
- Elevated Random Office BP Measurement

**Figure 7. Assessment of patients with hypertension**

Adapted from: CHEP 2014 Guidelines

**Treatment**

- target BP is <140/90 mmHg, <130/80 mmHg if DM
- lifestyle modification (in all HTN patients)
  - may be sufficient in patients with stage 1 HTN (140-159/90-99)
  - diet
    - follow Dietary Guidelines for Americans (see Nutrition, FM6) and Dietary Approaches to Stop HTN (DASH) (reduced cholesterol and saturated fats)
    - limit daily sodium intake to 65-100 mmol (1.5-2.3 g)
    - potassium/magnesium/calcium supplementations are NOT recommended for HTN
  - moderate intensity dynamic exercise: 30-60 min, 4-7 x/wk; higher intensity exercise is no more effective
  - smoking cessation
  - stress management
  - low-risk alcohol consumption (see Alcohol, FM12)
  - achieve and maintain a healthy BMI (18.5-24.9 kg/m²) and waist circumference (<40.2 in for men, <34.6 in for women); use multidisciplinary approach to weight loss
  - individualized cognitive behavioral interventions for stress management
- pharmacological
  - indications regardless of age (caution with elderly patients)
    - dBP ≥90 mmHg with target organ damage or independent cardiovascular risk factors
    - dBP ≥100 mmHg or sBP ≥160 mmHg without target organ damage or cardiovascular risk factors
    - sBP ≥140 with target organ damage
  - first line antihypertensives: thiazide/thiazide-like diuretic, ACEI (for non-African patients), ARB, long-acting CCB, β-blocker (if age <60)
  - if partial response to standard dose monotherapy, add another first-line drug
  - caution with combination of non-DHP CCB and β-blocker
  - combination of ACEI and ARB is not recommended
  - be cautious of hypokalemia in patients treated with thiazide/thiazide-like diuretic monotherapy
  - if still not controlled or adverse effects, can add other classes of anti-hypertensives
### Table 24. Pharmacologic Treatment of Hypertension in Patients with Unique Conditions

- β-blocker
- CCB
- Diuretic

**Thiazides as First-Line Antihypertensive Therapy – ALLHAT**

*JAMA 2002;288:2981-2997*

- **Study:** Randomized, double-blind, active-controlled clinical trial with mean follow-up of 4.9 yr.
- **Patients:** 33,357 participants (mean age 47 yr; 53% male, 47% white) with stage 1 or 2 HTN and at least one other CHD risk factor.
- **Intervention:** Participants were randomly assigned to receive chlorthalidone (12.5-25 mg/d), amlodipine (2.5-10 mg/d), or lisinopril (10-40 mg/d). Target BP was <140/90 mmHg, achieved by titrating the assigned study drug, and adding open-label agents when necessary.
- **Outcomes:** The primary outcome was combined fatal CHD or non-fatal MI. Secondary outcomes were all-cause mortality, stroke, combined CHD, and combined CVD.
- **Results:** There were no significant differences in either the primary outcome or all-cause mortality between treatment groups. For amlodipine vs. chlorthalidone, secondary outcomes were similar except for a higher 6 yr rate of heart failure with amlodipine (10.2% vs. 7.7%; p<0.001). For lisinopril vs. chlorthalidone, lisinopril had higher 6 yr rates of combined CVD (33.3% vs. 30.9%; p<0.001), stroke (6.3% vs. 5.6%; p=0.02) and heart failure (6.7% vs. 7.7%; p<0.001).
- **Conclusion:** Thiazide diuretics are superior to CCB and ACEI for preventing one or more major forms of CVD, with similar risks of death and non-fatal MI.
Follow-Up
- assess and encourage adherence to pharmacological and non-pharmacological therapy at every visit
- lifestyle modification → q3-6mo
- pharmacological
  - q1-2mo until BP under target for 2 consecutive visits
  - more often for symptomatic HTN, severe HTN, antihypertensive drug intolerance, target organ damage
  - q3-6mo once at target BP
- referral is indicated for cases of refractory HTN, suspected secondary cause or worsening renal failure
- hospitalization is indicated for malignant HTN

History
- number of joints involved: monoarticular, oligoarticular, polyarticular
- pattern of joints involved: symmetrical vs. asymmetrical, large vs. small joints, axial skeleton
- onset: acute vs. chronic (>6 wk)
- trauma, infection, medications (steroids, diuretics)
- morning stiffness (duration) vs. worse at end of day
- FHx of arthritis
- comorbidities: DM (carpal tunnel syndrome), renal insufficiency (gout), psoriasis (psoriatic arthritis), myeloma (low back pain), osteoporosis (fracture), obesity (OA)
- constitutional symptoms (neoplasm)

Physical Exam
- vitals
- specific joint exams
- systemic features (skin, nails, eyes, hands)

Investigations (Guided by the History and Physical Exam)
- general: CBC and differential, electrolytes, Cr
- acute phase reactants: ESR, CRP, ferritin, albumin, fibrinogen
- complement (C3, C4)
- urinalysis to detect disease complications (proteinuria, active sediment)
- serology (ANA, anti-dsDNA, HLA-B27, anti-Jo-1, anti-Sm, anti-La, anti-Ro, RhF, and anti-CCP, etc.)
- synovial fluid analysis (cell count + differential, culture, Gram stain, microscopy)
- tissue cultures
- radiology (plain film, CT, MRI, U/S, bone densitometry, angiography, bone scan)

Signs and Symptoms of Inflammatory Arthritis

WARM(S) Joints
- Worse with rest, better with activity
- Awakening in the latter half of the night
- Redness around joint
- Morning stiffness (>30 min)
- Soft tissue swelling, erythema

Systemic Features
- Fever (SLE, infection)
- Rash (SLE, psoriatic arthritis)
- Nail abnormalities (psoriatic, reactive arthritis)
- Uveitis (psoriatic, reactive arthritis, ankylosing spondylitis)
- Myalgias (fibromyalgia, myopathy)
- Weakness (polymyositis, neuropathy)
- GI symptoms (scleroderma, IBD)
- GU symptoms (reactive arthritis, gonococccemia)
Treatment

- patient education including lifestyle modifications
- physiotherapy, occupational therapy
- manage pain (acetaminophen, NSAIDs)
- treat specific causes (e.g. antibiotics, DMARDs etc., see Rheumatology, RH30)

Low Back Pain

- see Orthopedics, OR23
- see https://www.bigbackpain.com for more information

Definition

- acute: <6 wk
- subacute: 6-12 wk
- chronic: >12 wk

Epidemiology

- 5th most common reason for visiting a physician
- lifetime prevalence: 90%
- peak prevalence: age 45-60
- most common cause of chronic disability for individuals <45 yr old
- 90% resolve in 6 wk, <5% become chronic

Etiology

- source of pain can be local, radicular, referred, or related to a psychiatric illness
- 98% are mechanical causes
  - pain is worse with movement, better with rest
  - sprain (ligament), strain (muscle), facet joint degeneration, disc degeneration/herniation, spinal stenosis (e.g. spondylosis), spondylolysis, compression fracture, pregnancy
- 2% are non-mechanical causes
  - most concerning when pain is worst at rest and does not change with position
  - surgical emergencies:
    - cauda equina syndrome (areflexia, lower extremity weakness, decreased anal tone, saddle anesthesia, fecal incontinence, urinary retention), AAA (pulsatile abdominal mass)
  - medical conditions
    - neoplastic (primary, metastatic, multiple myeloma)
    - infectious (osteomyelitis, TB)
    - metabolic (osteoporosis, osteomalacia, Paget’s disease)
    - rheumatologic (ankylosing spondylitis, polymyalgia rheumatica)
    - referred pain (perforated ulcer, pancreatitis, pyelonephritis, ectopic pregnancy, herpes zoster)

Physical Exam

- inspection: curvature, posture, gait
- palpation: bony deformities/tenderness, paraspinal muscle bulk/tenderness, trigger points
  - percussion of spine to elicit pain due to fracture or infection
- ROM and peripheral pulses
- neurologic exam for L4/L5/S1 helps determine level of spinal involvement (power, reflexes, sensation)
- special tests
  - straight leg raise (positive if pain at <70 degrees and aggravated by ankle dorsiflexion), positive test is indicative of sciatica
  - crossed straight leg raise (raising of uninvolved leg elicits pain in leg with sciatica), more specific than straight leg raise
  - femoral stretch test (patient prone, knee flexed, examiner extends hip) to diagnose L4 radiculopathy

Investigations

- plain films not recommended in initial evaluation
- if infection/cancer suspected: CBC, ESR
- if neurologic deficits worsening or infection/cancer suspected: consider CT or MRI

Indications for Lumbar Spine X-Ray

- No improvement after 6 wk
- Fever >100.4°F
- Unexplained weight loss
- Prolonged corticosteroid use
- Significant trauma
- Progressive neurological deficit
- Suspicion of ankylosing spondylitis
- History of cancer (rule out metastases)
- Alcohol/drug abuse (increased risk of osteomyelitis, trauma, fracture)
A Summary of the Guideline for the Evidence-Informed Primary Care Management of Low Back Pain

**Red Flags** help identify rare, but potentially serious conditions. They include:
- Features of Cauda Equina Syndrome including sudden onset of loss of bladder/bowel control, saddle anesthesia (EMERGENCY)
- Severe worsening pain, especially at night or when lying down (URGENT)
- Significant trauma (URGENT)
- Use of steroids or intravenous drugs (URGENT)
- Patient with first episode over 50 years old, especially over 65 (SOON)
- Widespread neurological signs (SOON)

**Yellow Flags** indicate psychosocial barriers to recovery. They include:
- Belief that pain and activity are harmful
- Tension behaviors (Was extended out)
- Low or negative mood, social withdrawal
- Treatment expectations that do not fit best practice
- Problems with claim and compensation
- History of back pain, time-off, other claims
- Problems at work, poor job satisfaction
- Heavy work, unproductive hours (shift work)
- Overprotective family or lack of support

**ACUTE and SUBACUTE** (within 12 weeks of pain onset)

- **1 – 6 WEEKS**
  - Educate patient that low back pain typically resolves within a few weeks (70% in 2 wks, 90% in 6 wks)
  - Prescribe self-care strategies including alternating cold and heat, continuation of usual activities as tolerated
  - Encourage early return to work
  - Recommended physical activity and/or exercise
  - Consider analgesics in this order:
    - Acetaminophen (1st line)
    - NSAIDs (2nd line)
    - Short-acting opioids
  - Spinal traction, TENS not recommended

- **Reassess (including Red Flags) if patient is not returning to normal function or symptoms are worsening**

- **Consider Referral**
  - Physical therapist
  - Chiropractor
  - Osteopathic physician
  - Physician specializing in musculoskeletal medicine
  - Spinal surgeons (for unremitting radicular symptoms)
  - Multidisciplinary pain program (if not returning to work)

**CHRONIC** (more than 12 weeks since pain onset)

- **Prescribe physical or therapeutic exercise**
  - **Analogic Options**
    - Acetaminophen
    - NSAIDs (consider PPI)
    - Low-dose tri cyclic antidepressants
    - Short-term benzodiazepine for flare-ups
  - **Referral Options**
    - Community-based active rehabilitation program
    - Community-based self-management/cognitive behavioral therapy program
  - **Additional Options**
    - Progressive muscle relaxation
    - Acupuncture
    - Massage therapy, TENS as adjunct to active therapy
    - Aqua therapy and yoga

**MODERATE TO SEVERE PAIN**

- **Spinal (for appropriate patients; refer to the Canadian National Spinal Guidelines endorsed by the College of Physicians and Surgeons of Alberta [http://nationalpaincentre.ucalgary.ca/spinal])**
- **Referral Options**
  - Multidisciplinary chronic pain program
  - Epidural steroids (for short-term relief of radicular pain)
  - Prolotherapy, facet joint injections, and surgery in carefully selected patients

**Figure 8. Low back pain treatment**

Menopause/Hormone Replacement Therapy

- see Gynecology, GY31

Epidemiology
- mean age of menopause = 51.4 yr
- a woman will spend over 1/3 of her life in menopause

Clinical Features
- associated with estrogen deprivation
- urogenital tract: atrophy, vaginal dryness/itching, urinary frequency/urgency/incontinence, bleeding
- blood vessels and heart: vasomotor instability (e.g. hot flashes), increased risk of heart disease
- bones: bone loss, joint/muscle/back pain, fractures, loss of height
- brain: depression, irritability, mood swings, memory loss

Management
- encourage physical exercise, smoking cessation, and a balanced diet with adequate intake/supplementation of calcium (1,200-1,500 mg/d) and vitamin D (800-2,000 IU/d)
- hormone replacement therapy (HRT)
  - prescribe for moderate to severe symptoms for no longer than 5 yr; routine use is not recommended
  - regimens: cyclic estrogen-progestin, continuous estrogen-progestin, estrogen only (if no uterus), estrogen patch/gel/cream/ring/vaginal tablet
  - decreases risk of osteoporotic fractures, colorectal cancer
  - increases risk of breast cancer, coronary heart disease, stroke, DVT, and PE
  - initiation of HRT requires a thorough discussion of short- and long-term benefits and risks
- consider venlafaxine, SSRIs, or gabapentin to ease vasomotor instability

Osteoarthritis

- see Rheumatology, RH5

Epidemiology
- most common form of arthritis seen in primary care
- prevalence is 10-12% and increases with age
- results in long-term disability in 2-3% of patients with OA
- almost everyone over the age of 65 shows signs of OA on x-ray, but only 33% of these individuals will be symptomatic

Clinical Features
- joint pain with activity, improved with rest, morning stiffness or gelling <30 min
- deformity, bony enlargement, crepitus, limitation of movement, periarticular muscle atrophy
- usually affects distal joints of hands, spine, hips, and knees

Investigations
- no laboratory tests for the diagnosis of OA
- hallmark radiographic features: joint space narrowing, subchondral sclerosis, subchondral cysts, osteophytes

Management
- goals: relieve pain, preserve joint motion and function, prevent further injury
- conservative
  - patient education, weight loss, low-impact exercise (OT/PT), assistive devices (e.g. canes, orthotics, raised toilet seats)
- pharmacological
  - consider comorbidities such as PUD, HTN, IHD, hepatic disease, and renal disease
  - medications do not alter natural course of OA
  - 1st line: acetaminophen up to 4 g/d (OA is not an inflammatory disorder)
  - 2nd line: NSAIDs in the lowest effective dose for the shortest duration of time, along with gastroprotection: COX-2 selective inhibitors (celecoxib/Celebrex, Meloxicam/Mobic®) are recommended if long-term treatment or if high risk for serious GI problems
  - combination analgesics (e.g. acetaminophen and codeine)
  - intra-articular hyaluronic acid injections
  - intra-articular corticosteroid injections (no more than 3-4x/yr) may be helpful in acute flares (benefits last 4-6 wk, can be up to 6 mo)
  - topical NSAID (diclofenac/Pennsaid®)
  - capsaicin cream (Zostrix®)
  - oral glucosamine
  - surgery
  - consider if persistent significant pain and functional impairment despite optimal pharmacotherapy (e.g. debridement, osteotomy, total joint arthroplasty)

Glucosamine Therapy for Treating Osteoarthritis
This meta-analysis of 25 single- and double-blinded randomized controlled trials with 4,963 patients compared glucosamine treatment, administered by any route, against placebo or another treatment.

Conclusions: Glucosamine can decrease pain and functional impairment resulting from OA and is not associated with any side effects compared to placebo. Differences in the effectiveness of Rotta and non-Rotta preparations highlight variability between glucosamine preparations and patients should be made aware of this.
Osteoporosis

- see Endocrinology, E42

- for current guidelines and tools see National Osteoporosis Foundation: http://nof.org/hcp/clinicians-guide

- age-related disease characterized by decreased bone mass and increased susceptibility to fractures

- about 9.9 million Americans are affected by osteoporosis, while an additional 43.1 million have low bone density

- approximately 1 in 2 women and up to 1 in 4 men ≥50 yr will sustain fractures due to osteoporosis

**Management**

- see Endocrinology, E44

**Palliative and End-of-Life Care**

- see Geriatrics, GM12
Rash

- see Dermatology, D5

ATOPIC DERMATITIS
- clinical features
  - affects all ages but is more common in children
  - pruritus is the most common symptom; scratching worsens the rash creating a vicious cycle
- treatment
  - goals: limit itching, repair skin
  - moisturizers, emollients, topical corticosteroids; oral corticosteroids and topical calcineurin inhibitors may be used

SEBORRHEIC DERMATITIS
- clinical features
  - affects all ages but is most common in infants within the first 3 mo of life (e.g. pityriasis capitis or "cradle cap") and adults age 30-60
  - affects the scalp, central face, and anterior chest; often presents as scalp scaling (dandruff) in adolescents and adults
  - may cause mild to marked erythema of the nasolabial fold, often with greasy scaling
- treatment
  - topical antifungals, topical low-potency steroids; topical calcineurin inhibitors may be used

ROSACEA
- clinical features
  - stages: (1) facial flushing, (2) erythema and/or edema and ocular symptoms, (3) papules and pustules, (4) rhinophyma
- treatment
  - topical or oral antibiotics, oral retinoids
  - laser treatment may be an option for progressive telangiectasia or rhinophyma
  - referral may be required to manage rhinophyma, ocular complications, or severe disease

ACNE VULGARIS
- clinical features
  - types: (I) comedonal, (II) papular, (III) pustular, (IV) nodulocystic
  - predilection for the face, neck, upper chest, and back
- treatment
  - mild acne: topical treatments (antibiotics, benzoyl peroxide, retinoids)
  - moderate acne: after topical treatments have failed, add oral antibiotics and consider hormonal therapy
  - severe acne: consider systemic retinoids

ONYCHOMYCOSIS (TINEA UNGUIUM)
- definition: fungal infection of the nail bed, matrix, or plate
- clinical features
  - occurs primarily in adults, most commonly after age 60
  - crumbling, distally dystrophic nails; yellowish, opaque with subungual hyperkeratotic debris
  - toenails are affected more often than fingernails
- investigations
  - microscopy of subungual scrapings under KOH preparation, culture
- treatment
  - oral antifungals (terbinafine/Lamisil®, itraconazole/Sporanox®), topical antifungals (ciclopirox/Loprox®)
Sexually Transmitted Diseases

Definition
- diverse group of infections caused by multiple microbial pathogens
- transmitted by either secretions or fluids from mucosal surfaces

Epidemiology
- high incidence rates worldwide
- American prevalence in clinical practice
  - common: chlamydia (most common), gonorrhea (2nd most common), HPV, genital herpes (increasing incidence of chlamydia and gonorrhea)
  - less common: hepatitis B, HIV, and syphilis (increasing in incidence), trichomoniasis
  - rare: chancroid, granuloma inguinale, lymphogranuloma venerum
- non-sexually transmitted genital tract infections: vulvovaginal candidiasis (VVC), bacterial vaginosis (BV)
- three most common infections associated with vaginal discharge in adult women are BV, VVC, and trichomoniasis

History
- sexual history
  - age of first intercourse, sexual orientation, sexual activity (oral, anal, and/or vaginal intercourse), sexual activity during travel
  - total number of partners in the past yr/mo/wk and duration of involvement with each
- STD history
  - STD awareness, contraception, previous STDs and testing (including Pap tests), partner communication regarding STDs
  - local symptoms such as burning, itching, discharge, sores, vesicles, testicular pain, dysuria, abdominal pain
  - systemic symptoms such as fever, lymphadenopathy, arthralgia

Investigations/Screening
- individuals at increased risk, even those who are asymptomatic, should be screened for chlamydia, gonorrhea, hepatitis B, HIV, and syphilis
- Pap test if none performed in the preceding 12 mo

Management
- primary prevention is vastly more effective than treating STDs and their sequelae
- offer hepatitis B vaccine if not immune, offer Gardasil® to women under age 26
- discuss STD risk factors (e.g. decreasing the number of sexual partners)
- direct advice to ALWAYS use condoms or to abstain from intercourse
- condoms are not 100% effective against HPV or HSV
- an STD patient is not considered treated until the management of his/her partner(s) is ensured (contact tracing by Public Health)
- patients diagnosed with bacterial STD or trichomonal infection should abstain from sexual activity until treatment completion and for 7 d after treatment for both partners, or until test of cure completed
- mandatory reporting: chlamydia, gonorrhea, hepatitis B, HIV, syphilis

When an STD is detected in a prepubertal child, evaluation for sexual abuse is mandatory

STD Risk Factors
-Sexually active males and females < 25 yr old
- Unprotected sex, sexual contact with a known case of STD, previous STD
- New sexual partner or > 2 sexual partners in the past 12 mo
- Street involved, homeless, and/or substance abuse

Sexual History
5 P’s
- Partners (numbers, gender)
- Practices (vaginal, oral, anal insertive/receptive)
- Protection
- Past history of STDs
- Pregnancy prevention

Prophylactic Vaccination Against Human Papillomavirus Infection and Disease in Women: A Systematic Review of Randomized Controlled Trials

CMAJ 2007;177:469-479

Purpose: To evaluate prophylactic HPV vaccination in preventing high- and low-grade cervical lesions, persistent HPV infection, external genital lesions, adverse events, and death using meta-analysis.

Studies: 9 reports from 6 different trials with 40,323 patients were included and all studies were of high methodologic quality. Three studies used the quadrivalent vaccine, two used the bivalent, and one used a monovalent. The longest mean duration of follow-up was 48 mo.

Results: Prophylactic HPV vaccination decreased the frequency of high-grade cervical lesions caused by vaccine-type HPV strains compared to the control group (OR 0.14; 95% CI 0.09-0.21). Vaccinations also prevented persistent HPV infection, low-grade lesions and genital warts, and the reported adverse events were mostly minor. Compared to placebo, there was no difference in serious adverse events or death.

Conclusion: Prophylactic HPV vaccination is highly efficacious in preventing infection and precancerous cervical disease in women aged 15-25 who have not previously been infected with vaccine-type HPV strains.
**Signs and Symptoms**

**Gonococcal Urethritis/Cervicitis (Neisseria gonorrhoeae)**
- M: urethral discharge, unexplained pyuria, dysuria, irritation, testicular swelling, 5x of epididymitis
- F: mucopurulent endocervical discharge, vaginal bleeding, dysuria, pelvic pain, dyspareunia
- M and F: often asymptomatic, can involve rectal symptoms in cases of unprotected anal sex

**Non-Gonococcal Urethritis/Cervicitis (Usually Chlamydia trachomatis)**
- ~70% asymptomatic
- If symptoms appear (usually 2-6 wk after infection) then similar to gonococcal symptoms (see above)

**Human Papillomavirus (genital warts, cervical dysplasia)**
- Most are asymptomatic
- M: cauliflower lesions (condylomata acuminata) on skin/mucosa of penile or anal area
- F: cauliflower lesions and/or pre-neoplastic/neoplastic lesions on cervix/vagina/vulva

**Genital Herpes (HSV-1 and -2)**
- 1° episode: painful vesiculocellular genital lesions ± fever, tender lymphadenopathy, protracted course
- Recurrent episodes: less extensive lesions, shorter course may have “trigger factors”

**Infectious Syphilis (Treponema pallidum)**
- 1°: chancre (painless sore), regional lymphadenopathy
- 2°: rash and flu-like symptoms, meningoitis, H/A, urethritis, retinitis, condyloma lata, mucus lesions, alopecia
- Latent Phase: asymptomatic
- 3°: neurologic, cardiovascular, and tissue complications

**Investigations**

- Specimen collection from 1° and 2° lesions, screen for culture, type-specific serologic testing for HSV-1 vs. HSV-2 antibodies and to determine 1° vs. recurrent episode

**Treatment**

- 1° episode:
  - Acyclovir 200 mg PO 5x/d x 5-10 d or
  - Famciclovir 250 mg PO tid x 5 d or
  - Valacyclovir 1,000 mg PO bid x 10 d

- Recurrent Episode:
  - Acyclovir 200 mg PO 5x/d x 5d or 800 mg PO tid x 2 d or
  - Famciclovir 125 mg PO bid x 5 d or
  - Valacyclovir 500 mg PO bid x 3 d or 1,000 mg PO OD x 3 d

**Complications**

- Chronic neurologic and cardiovascular sequelae, increased risk of acquiring and transmitting HIV

**F = females; M = males**

*NB: if urethritis/cervicitis is suspected, always treat for both gonococcal and non-gonococcal types (i.e. ceftriaxone AND azithromycin)*

---

**Sinusitis**

- see Otolaryngology, OT25

**Etiology**

- viral etiology is more common
- viral: rhinovirus, influenza, parainfluenza
- bacterial: S. pneumoniae, H. influenzae, M. catarrhalis

**Management of Acute Sinusitis**

- may provide symptom relief: oral analgesics (acetaminophen, NSAIDs), nasal saline rinse, short-term use of topical or oral decongestants
- do not prescribe antihistamines
- intra-nasal corticosteroids if diagnosed with mild to moderate acute bacterial sinusitis
- antibiotics and intra-nasal corticosteroids if diagnosed with severe acute bacterial sinusitis
- ENT referral if: anatomic defect (e.g. deviated septum, polyp, adenoid hypertrophy), failure of second-line therapy, >4 episodes/yr, development of complications (e.g. mucocele, orbital extension, meningitis, intra-cranial abscess, venous sinus thrombosis)
Sleep Disorders

- see Respirology, R31 and Neurology, N45

Definition
- most often characterized by one of three complaints:
  - insomnia
    - difficulty falling asleep, difficulty maintaining sleep, early-morning wakening, non-refreshing sleep
  - parasomnias
    - night terrors, nightmares, restless leg syndrome, somnambulism (performing complex behavior during sleep with eyes open but without memory of event)
    - excessive daytime sleepiness

Epidemiology
- 1/3 of patients in primary care setting have occasional sleep problems, 10% have chronic sleep problems
Etiology
- primary sleep disorders
  - primary insomnia, narcolepsy, obstructive sleep apnea, restless leg syndrome, periodic limb movements of sleep
- secondary causes
  - medical: COPD, asthma, CHF, hyperthyroidism, chronic pain, BPH, menopause, GERD, PUD, pregnancy, neurological disorders
  - drugs: alcohol, caffeine, nicotine, nicotine replacement therapy, β-agonists, antidepressants, steroids
  - psychiatric: mood and anxiety disorders
  - lifestyle factors: shift work, jet-lag

Investigations
- complete sleep diary every morning for 1-2 wk
  - record bedtime, sleep latency, total sleep time, awakenings, quality of sleep
- rule out specific medical problems (e.g. CBC and differential, TSH)
- refer for sleep study, nocturnal polysomnogram, or daytime multiple sleep latency test if suspicion of sleep apnea or periodic leg movements of sleep

Treatment of Specific Problems
- primary insomnia
  - majority of cases
  - person reacts to insomnia with fear or anxiety around bedtime or with a change in sleep hygiene, which can progress to a chronic disorder (psychophysiological insomnia)
  - treat any suspected medical or psychiatric cause
  - behavior based treatment
    - sleep hygiene: avoid alcohol, caffeine, nicotine; comfortable sleep environment; regular sleep schedule; no napping
    - exercise regularly, avoid heavy exercise within 3 h of bedtime
    - relaxation therapy: deep breathing, meditation, biofeedback
    - stimulus control therapy: re-association of bed/bedroom with sleep, re-establishment of a consistent sleep-wake schedule, reduce activities that cue staying awake
    - sleep restriction therapy: total time in bed should closely match the total sleep time of the patient (improves sleep efficacy)
    - CBT: address inappropriate beliefs and attitudes that perpetuate dysfunctional sleep
  - pharmacologic treatment
    - short-acting benzodiazepines (e.g. lorazepam, oxazepam, temazepam) at the lowest effective dose should be used <7 consecutive nights to break cycle of chronic insomnia or to manage an exacerbation of previously controlled primary insomnia
    - non-benzodiazepines: eszopiclone (Lunesta®), zolpidem (Ambien®), melatonin, low dose anti-depressants with sedating properties (amitriptyline, trazadone, mirtazapine)
    - follow-up every 2-4 wk initially (to reinforce behavioral interventions and renew/consider pharmacotherapy) then every 3 mo; if no progress or limited improvement, consider referral to sleep medicine program
- snoring
  - results from soft tissue vibration at the back of the nose and throat due to turbulent airflow through narrowed air passages
  - physical exam: obesity, nasal polyps, septal deviation, hypertrophy of the nasal turbinates, enlarged uvula and tonsils
  - investigations (only if severely symptomatic): nocturnal polysomnography and airway assessment (CT/MRI)
  - treatment
    - sleep on side (position therapy), weight loss
    - nasal dilators (noninvasive external dilator made with elastic adhesive backing applied over nasal bridge), tongue-retaining devices, mandibular advancement devices
  - at risk of developing obstructive sleep apnea
- obstructive sleep apnea (OSA)
  - apnea (no breathing for ≥10 s) resulting from upper airway obstruction due to collapse of the base of the tongue, soft palate with uvula, and epiglottis; respiratory effort is present
  - leads to a distinctive snorting, choking, awakening type pattern as the body rouses itself to open the airway (resuscitative breath)
  - apneic episodes can last from 20 s to 3 min and occur 100-600 episodes/night
  - diagnosis is based on nocturnal polysomnography: >15 apneic/hypopneic episodes per h of sleep with arousal recorded
  - consequences
    - daytime somnolence, non-restorative sleep
    - poor social and work performance
    - mood changes: anxiety, irritability, depression
    - sexual dysfunction: poor libido, impotence

Risk Factors for Obstructive Sleep Apnea
- 2% of women, 4% of men between ages 30-60
- Obesity (due to upper airway narrowing). BMI >28 kg/m² present in 60-90% of cases
- Children (commonly due to large tonsils and adenoids)
- Aging (due to decreased muscle tone)
- Persistent URIs, allergies, nasal tumors, hypothyroidism (due to macroglia), neuromuscular disease
- Family history
morning headache (due to hypercapnia)
• HTN (2x increased risk), CAD (3x increased risk), stroke (4x increased risk), arrhythmias
• pulmonary HTN, right ventricular dysfunction, cor pulmonale (due to chronic hypoxemia)
• memory loss, decreased concentration, confusion

investigations
• evaluate BP, inspect nose and oropharynx (enlarged adenoids or tonsils)
• blood gas not helpful, TSH if clinically indicated
• nocturnal polysomnography

treatment
• modifiable factors: avoid sleeping supine; weight loss; avoid alcohol, sedatives, opioids; inhaled steroids if nasal swelling present; dental appliances to modify mandibular position
• primary treatment of OSA is CPAP: maintains patent airway in 95% of OSA cases
• surgery: somnoplasty, uvulopalatopharyngoplasty (UPPP), tonsillectomy, and adenoidectomy (in children)
• report patient to Ministry of Transportation if OSA is not controlled by CPAP

Sore Throat (Pharyngitis)

Definition
• inflammation of the oropharynx
• may be caused by a wide range of infectious organisms, most of which produce a self-limited infection with no significant sequelae

Etiology
• viral: adenovirus, rhinovirus, influenza virus, RSV, EBV, coxsackie virus, herpes simplex virus, CMV, HIV
• bacterial: group A β-hemolytic Streptococcus (GABHS), group C and group β-hemolytic Streptococcus, Neisseria gonorrhoeae, Chlamydia pneumoniae, Mycoplasma pneumoniae, Corynebacterium diphtheriae

Epidemiology
• viral
  • most common cause (90% in adults is viral), occurs year round
• bacterial
  • GABHS
    • most common bacterial cause
    • occurs most often in winter months
    • 5-15% of adult cases and up to 50% of all pediatric cases of acute pharyngitis
    • most prevalent between 5-17 yr old

Clinical Features
• viral
  • pharyngitis, conjunctivitis, rhinorrhea, hoarseness, cough
  • nonspecific flu-like symptoms such as fever, malaise, and myalgia
  • often mimics bacterial infection
  • EBV (infectious mononucleosis)
    • pharyngitis, tonsillar exudate, fever, lymphadenopathy, fatigue, rash
  • coxsackie virus (hand, foot, and mouth disease)
    • primarily late summer, early fall
    • sudden onset of fever, pharyngitis, headache, abdominal pain, and vomiting
    • appearance of small vesicles that rupture and ulcerate on soft palate, tonsils, pharynx
    • ulcers are pale gray and several mm in diameter, have surrounding erythema, and may appear on hands and feet
  • herpes simplex virus
    • like coxsackie virus but ulcers are fewer and larger
  • pharyngitis, tonsillar exudate, fever, lymphadenopathy, fatigue, rash
• bacterial
  • symptoms: pharyngitis, fever, malaise, headache, abdominal pain, absence of cough
  • signs: fever, tonsillar or pharyngeal erythema/exudate, swollen/tender anterior cervical nodes, halitosis
  • complications: rheumatic fever, glomerulonephritis, suppurative complications (abscess, sinusitis, otitis media, cervical adenitis, pneumonia), meningitis, impetigo

Red Flags in Patients with “Sore Throat”
• Persistence of symptoms longer than 1 wk without improvement
• Respiratory difficulty (particularly stridor, croup, etc.)
• Difficulty in handling secretions (peritonsillar abscess)
• Difficulty in swallowing (Ludwig’s angina)
• Severe pain in the absence of erythema (supraglottitis/epiglottitis)
• Palpable mass (neoplasm)
• Blood in the pharynx or ear (trauma)
Investigations

- suspected GABHS
  - see Table below for approach to diagnosis and management of GABHS
  - gold standard for diagnosis is throat culture
  - rapid test for streptococcal antigen: high specificity (95%) but low sensitivity (50-90%)
  - suspected EBV (infectious mononucleosis)
    - peripheral blood smear, heterophile antibody test (i.e. the latex agglutination assay or "monospot")

| Table 28. Modified Centor Score: Approach to Diagnosis and Management of GABHS |
|---------------------------------|---------------------------------|---------------------------------|---------------------------------|
| POINTS                          | 1                              | 2                              | 3                              |
| Cough absent?                   | 1                              |                                |                                |
| History of fever > 100.4°F?    | 1                              |                                |                                |
| Tonsillar exudate?             | 1                              |                                |                                |
| Swollen, tender anterior nodes?| 1                              |                                |                                |
| Age 3-14                        | 1                              |                                |                                |
| Age 15-44                       | 0                              |                                |                                |
| Age > 45                        | -1                             |                                |                                |

In communities with moderate levels of strep infection (10-20% of sore throats):

<table>
<thead>
<tr>
<th>Score</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4 or more</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chance patient has strep</td>
<td>1-2.5%</td>
<td>5-10%</td>
<td>11-17%</td>
<td>28-35%</td>
<td>51-53%</td>
</tr>
<tr>
<td>Suggested action</td>
<td>NO culture or antibiotic</td>
<td>Culture all, treat with antibiotics only if culture is positive</td>
<td>Culture all, treat with antibiotics on clinical grounds¹, discontinue antibiotics if culture comes back negative</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

¹Clinical grounds include a high fever or other indicators that the patient is clinically unwell and is presenting early in the course of the illness

Limitations: *This score is not applicable to patients less than 3 yr of age
* If an outbreak or epidemic of illness caused by GABHS is occurring in any community, the score is invalid and should not be used

Management

- viral pharyngitis
  - antibiotics not indicated
  - symptomatic therapy: acetaminophen/NSAIDs for fever and muscle aches, decongestants

- GABHS
  - antibiotic treatment decreases severity and duration of symptoms, risk of transmission (after 24 h of treatment), and risk of rheumatic fever and suppurative complications
  - incidence of glomerulonephritis is not decreased with antibiotic treatment
  - no increased incidence of rheumatic fever with 48 h delay in antibiotic treatment; if possible, delay antibiotic treatment until culture confirms diagnosis
  - routine F/U and/or post-treatment throat cultures are not required for most patients
  - F/U throat culture only recommended for: patients with history of rheumatic fever, patients of family member(s) with history of acute rheumatic fever, suspected streptococcal carrier

- infectious mononucleosis (EBV)
  - self-limiting course; antibiotics are not indicated
  - symptomatic treatment: acetaminophen/NSAIDs for fever, pharyngitis, malaise
  - avoid heavy physical activity and contact sports for at least 1 mo or until splenomegaly resolves because of risk of splenic rupture
  - if acute airway obstruction, give corticosteroids and consult ENT
Complementary and Alternative Medicine

Epidemiology
- 50-75% of Americans report some use of CAM over their lifetime, and only half will disclose this use to their physician
- more likely to be used by younger patients and those with higher education and income
- examples: chiropractic, acupuncture, massage, naturopathy, homeopathy, traditional Chinese medicine, craniosacral therapy, osteopathy

Herbal Products
- over 50% of Americans use natural health products (NHPs)
- most commonly used include echinacea, ginseng, ginkgo, garlic, St. John's wort, and soy
- relatively few herbal products have been shown to be effective in clinical trials
- many patients believe herbal products are inherently safe and are unaware of potential side effects and interactions with conventional medicines
- all NHPs must be regulated under The Natural Health Products Regulations as of January 1, 2004, including herbal remedies, homeopathic medicines, vitamins, minerals, traditional medicines, probiotics, amino acids, and essential fatty acids (e.g. omega-3)
- always ask patients whether they are taking any herbal product, herbal supplement, or other natural remedy. Further questions may include:
  - Are you taking any prescription or non-prescription medications for the same purpose as the herbal product?
  - Are you allergic to any plant products?
  - Are you pregnant or breastfeeding?
- information resources: National Center for CAM (www.nccam.nih.gov)

Overview of Gastrointestinal Tract

• the gastrointestinal tract runs from mouth to anus ("gum to bum")

Table 1. Summary of Gastrointestinal Tract Structure and Function

<table>
<thead>
<tr>
<th>Organ</th>
<th>Function</th>
<th>Blood Supply</th>
<th>Innervation</th>
<th>Histology and Structural Features</th>
</tr>
</thead>
<tbody>
<tr>
<td>Esophagus</td>
<td>• Muscular tube approximately 25 cm long with a diameter of 2 cm</td>
<td>• Arterial: left gastric artery and left inferior phrenic artery</td>
<td>• Parasympathetic innervation via anterior and posterior gastric nerves (vagal trunks)</td>
<td>• Mucosa: stratified squamous epithelium</td>
</tr>
<tr>
<td></td>
<td>• Extends from pharynx to the stomach</td>
<td>• Venous: Left gastric vein → portal venous system</td>
<td>• Sympathetic innervation via thoracic trunks of the greater splanchnic nerves</td>
<td>• Submucosa: connective tissue, lymphocytes, plasma cells, nerve cells</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Esophageal veins → aygos vein → IVC (systemic)</td>
<td></td>
<td>• Muscularis propria (muscularis externa): inner circular, outer longitudinal muscle</td>
</tr>
<tr>
<td>Stomach</td>
<td>• Delivers food to intestine for digestion and absorption</td>
<td>• Lesser curvature:</td>
<td>• Parasympathetic innervation via vagus nerve</td>
<td>• 5 parts:</td>
</tr>
<tr>
<td></td>
<td>• Secretes acid, probably to reduce enteric infections/pneumonia; facilitate digestion of protein/iron/B₁₂</td>
<td>• Right and left gastric arteries (from celiac trunk)</td>
<td>• Sympathetic innervation via celiac plexus (from T6-T9)</td>
<td>• Cardia</td>
</tr>
<tr>
<td></td>
<td>• Secretes intrinsic factor to facilitate B₁₂ absorption</td>
<td>• Greater curvature:</td>
<td></td>
<td>• Fundus</td>
</tr>
<tr>
<td></td>
<td>• Minor contribution to initial protein digestion via pepsin</td>
<td>• Right and left gastroesophageal (gastroepiploic) arteries (from gastroduodenal and splenic a. respectively)</td>
<td></td>
<td>• Body</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Fundus: short and posterior gastric arteries (from the splenic artery)</td>
<td></td>
<td>• Antrum</td>
</tr>
<tr>
<td>Duodenum</td>
<td>• Modulates enteral pH via secretin → decreased gastric acid secretion; increased bicarbonate secretion</td>
<td>• Branches of celiac artery and superior mesenteric artery</td>
<td>• Parasympathetic innervation via vagus nerve</td>
<td>• Pylorus</td>
</tr>
<tr>
<td></td>
<td>• Secretes CCK to stimulate bile secretion</td>
<td>• Parasympathetic innervation via greater and lesser splanchnic nerves</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Table 1. Summary of Gastrointestinal Tract Structure and Function (continued)

<table>
<thead>
<tr>
<th>Organ</th>
<th>Function</th>
<th>Blood Supply</th>
<th>Innervation</th>
<th>Histology and Structural Features</th>
</tr>
</thead>
<tbody>
<tr>
<td>Jejunum</td>
<td>• Absorption of sodium, water, and nutrients (protein, carbohydrates, fat, folic acid, and vit A, B, C, D, E, K)</td>
<td>• Superior mesenteric artery</td>
<td>• Parasympathetic innervation via fibers of the posterior vagal trunk</td>
<td>• Deep red color&lt;br&gt; • 2-4 cm in thickness&lt;br&gt; • Thick and heavy wall&lt;br&gt; • Plicae circulars are large, tall and closely packed&lt;br&gt; • Has long vasa recta&lt;br&gt; • Scant fat in mesentery&lt;br&gt; • Scant Peyer’s patches</td>
</tr>
<tr>
<td>Ileum</td>
<td>• Absorption of sodium, water, nutrients, soluble vitamins (only site of vit B₁₂ absorption), and bile salt (entero-hepatic circulation)</td>
<td>• Superior mesenteric artery</td>
<td>• Same as jejunum</td>
<td>When compared to jejunum:&lt;br&gt; • Paler pink color&lt;br&gt; • 2-3 cm in thickness&lt;br&gt; • Thin and light walls&lt;br&gt; • Plicae circulars are small and sparse&lt;br&gt; • Contains more mesenteric fat&lt;br&gt; • Many Peyer’s patches</td>
</tr>
<tr>
<td>Large Bowel</td>
<td>• Absorption of water (5-10% of total water)</td>
<td>• Branches of superior and inferior mesenteric arteries</td>
<td>• Parasympathetic innervation via vagus nerve&lt;br&gt; • Sympathetic innervation via greater and lesser splanchnic nerves</td>
<td>• Consists of cecum, colon (ascending, transverse, descending, and sigmoid), rectum and anal canal&lt;br&gt; • Features include tentiae coli, haustra, and omental appendices</td>
</tr>
<tr>
<td>Liver</td>
<td>• Glucose homeostasis&lt;br&gt; • Plasma protein synthesis&lt;br&gt; • Lipid and lipoprotein synthesis&lt;br&gt; • Bile acid synthesis and secretion&lt;br&gt; • Vitamin A, D, E, K, B₁₂, B₂₁₂, D, E, K storage&lt;br&gt; • Biotransformation, detoxification&lt;br&gt; • Excretion of compounds</td>
<td>• 2 sources&lt;br&gt; • Portal vein (75-80%)&lt;br&gt; • Hepatic artery (20-25%)</td>
<td>• Sympathetic innervation via fibers of the celiac plexus&lt;br&gt; • Parasympathetic innervation via fibers of the anterior and posterior vagal trunks</td>
<td>• Largest internal organ&lt;br&gt; • Composed of 4 lobes (left, right, caudate, quadrate) and divided into 8 segments</td>
</tr>
<tr>
<td>Biliary Tract</td>
<td>• Gallbladder functions to store and release bile that is produced in the liver&lt;br&gt; • Bile is used to emulsify fat and is composed of cholesterol, lecithin, bile acids, and bilirubin&lt;br&gt; • CCK stimulates gallbladder emptying while trypsin and chymotrypsin inhibit bile release</td>
<td>• Cystic artery</td>
<td>• Parasympathetic innervation via vagus nerve&lt;br&gt; • Sympathetic and visceral innervation via celiac nerve plexus&lt;br&gt; • Somatic afferent fibers via right phrenic nerve</td>
<td>• Consists of the hepatic ducts (intrahepatic, left, right and common), gallbladder, cystic duct, common bile duct, and ampulla of Vater&lt;br&gt; • Accessory pancreatic duct connecting to common bile duct prior to ampulla of Vater</td>
</tr>
<tr>
<td>Pancreas</td>
<td>• Endocrine function: islets of Langerhans produce glucagon, insulin, and somatostatin (from the α, β, and δ cells, respectively)&lt;br&gt; • Exocrine function: digestive enzymes are produced including amylase, lipase, trypsin, chymotrypsin, and carboxypeptidase</td>
<td>• Anterior superior pancreaticoduodenal artery (from the celiac trunk)&lt;br&gt; • Anterior inferior pancreaticoduodenal artery (from the superior mesenteric artery)&lt;br&gt; • Dorsal pancreatic artery (from the splenic artery)&lt;br&gt; • Pancreatic veins drain into the portal, splenic, and superior mesenteric veins</td>
<td>• Parasympathetic innervation via vagus nerve&lt;br&gt; • Sympathetic innervation via abdominal pelvic splanchnic nerves</td>
<td>• 4 parts of pancreas: head (includes uncinate process), neck, body, and tail&lt;br&gt; • (Major) pancreatic duct connecting to common bile duct prior to ampulla of Vater&lt;br&gt; • Accessory pancreatic duct connected directly to duodenum</td>
</tr>
</tbody>
</table>

**Visualizing the Gastrointestinal Tract**

- see Medical Imaging, MI10

**Esophagus, Stomach, Duodenum**

- OGD: best visualization of mucosa; also allows for therapeutic intervention (e.g. banding varices, thermal therapy/clipping/injecting bleeding ulcers, and dilatation e.g. esophageal strictures)
  - consider barium swallow first if dysphagia, decreased level of consciousness (increases risk of aspiration), inability to cooperate (increases risk of pharyngeal trauma during intubation)<br>  - endotracheal intubation first if massive upper GI bleed, acidemia, or inability to protect airway
Small Bowel
- most difficult to visualize, especially if mucosal detail is needed
- CT enterography more accurate than small bowel follow through, but both have low sensitivity
- MRI enterocolonoscopy increasingly available (use enterocolonoscopy if dilatation of the small bowel might improve sensitivity, such as diverticulosis, or if stricture suspected)
- "double balloon" enteroscopy (enteroscope with proximal and distal balloons to propel endoscope into jejunum from mouth or into jejunum/ileum or into ileus from anus) may be most sensitive but currently available only in selected centers; technically demanding
- wireless endoscopy capsule (26 x 11 mm capsule is swallowed, transmits images to a computer; contraindicated in bowel obstruction) is also accurate in diagnosis but unable to provide any therapeutic intervention

Colon and Terminal Ileum
- colonoscopy, with biopsy if required; contraindicated in perforation, acute diverticulitis, and severe colitis (increased risk of perforation)
- CT colonography ("virtual colonoscopy") more accurate in diagnosing diverticulosis, extrinsic pressure on colon (e.g. ovarian cancer compressing sigmoid colon), and fistulae; increasing evidence for use in colorectal cancer screening, especially for assessment of right side of colon in cases where colonoscopy is incomplete

Pancreatic/Biliary Duct
- MRCP almost as sensitive as ERCP in determining if bile duct obstruction present, but less accurate in determining cause of obstruction (tumor, stone, stricture)
- ERCP if endoscopic draining necessary, strong suspicion of stone, obstruction requiring stenting, or if tissue sampling required

**Esophagus**

**Gastroesophageal Reflux Disease**

**Definition**
- condition in which the stomach contents (most characteristically acid) moves backwards from the stomach into the esophagus (the tube from the mouth to the stomach)

**Etiology**
- inappropriate transient relaxations of LES – most common cause
- low basal LES tone (especially in scleroderma)
- contributing factors include: delayed esophageal clearance, delayed gastric emptying, obesity, pregnancy
- acid hypersecretion (rare): Zollinger-Ellison syndrome (gastrin-secreting tumor)
- hiatus hernia worsens reflux, does not cause it (see General Surgery, GS12)

**Clinical Features**
- "heartburn" (pyrosis) and acid regurgitation (together are 80% sensitive and specific for reflux) ± sour regurgitation, water brash, sensation of a lump in the throat (bolus sensation), and frequent belching
- non-esophageal symptoms (see G7) are increasingly recognized of being poor predictors of reflux

**Foods/Substances that Aggravate GERD Symptoms**
- EtOH
- Caffeine
- Tobacco
- Fatty/fried foods
- Chocolate
- Peppermint
- Spicy foods
- Citrus fruit juices

**Epigastric discomfort** = postprandial fullness, early satiety, epigastric pain, or burning

Figure 2. Signs and symptoms of GERD

Investigations
- Usually a clinical diagnosis based on symptom history and relief following a trial of pharmacotherapy (PPI: symptom relief 80% sensitive for reflux)
  - Absolute indications:
    - Heartburn accompanied by red-flags (bleeding, weight loss, etc.)
    - Persistent reflux symptoms or prior severe erosive esophagitis after therapeutic trial of 4-8 wk of PPI 2x daily
    - History of esophageal stricture with persistent dysphagia
- Repeat endoscopy indicated only if known Barrett’s (or recurrence of symptoms) because future likelihood of Barrett’s and esophagitis is minimal if the first endoscopy is normal
- Esophageal manometry (study of esophageal motility)
- May be done to diagnose abnormal peristalsis and/or decreased LES tone, but cannot detect presence of reflux; indicated before surgical fundoplication to intact esophageal function
- Surgical fundoplication (wrapping of gastric fundus around the lower end of the esophagus) more likely to be successful if lower esophageal pressure is diminished; less likely to be successful if abnormal peristalsis
- 24 h pH monitoring: most accurate test, but not required or performed in most cases
  - Most useful if PPIs do not improve symptoms

Management
- PPIs are the most effective therapy and usually need to be continued as maintenance therapy
- On-demand: antacids (Mg(OH)2, Al(OH)3, alginate), H2-blockers, or PPIs can be used for NERD
- Diet helps symptoms, not the disease; avoid alcohol, coffee, spices, tomatoes, and citrus juices
- Only beneficial lifestyle changes are weight loss (if obese) and elevating the head of bed (if nocturnal symptoms)
- Dyspepsia may recur if therapy is discontinued

Complications
- Esophageal stricture disease – scarring can lead to dysphagia (solids)
- Ulcer
- Bleeding
- Barrett’s esophagus and esophageal adenocarcinoma – gastroscopy is recommended for patients with chronic GERD or symptoms suggestive of complicated disease (e.g. anorexia, weight loss, bleeding, dysphagia)

Barrett’s Esophagus

Definition
- Metaplasia of normal squamous esophageal epithelium to abnormal columnar epithelium containing-type intestinal mucosa (intestinal metaplasia)

Etiology
- Thought to be acquired via long-standing GERD and consequent damage to squamous epithelium

Epidemiology
- In North America and Western Europe, 0.5-2.0% of adults are thought to have Barrett’s esophagus
- Up to 10% of GERD patients will have already developed BE by the time they seek medical attention
- More common in males, age >50, Caucasians, smokers, overweight, hiatus hernia, and long history of reflux symptoms

Pathophysiology
- Endoscopy shows erythematous epithelium in distal esophagus; diagnosis of BE relies on biopsy demonstrating the presence of specialized intestinal epithelium of any length within the esophagus
- BE predisposes to premalignant changes in abnormal columnar epithelium, characterized as low- or high-grade dysplasia

Screening and surveillance are critical as dysplasia, which is the most feared complication of BE, carries a variable risk of progression to adenocarcinoma.

diagram: Classification of gastroesophageal reflux disease

Gastroesophageal reflux disease (GERD)
- Non-erosive reflux disease (NERD)
- Normal esophagus
- Aim for symptom relief only; proton pump inhibitor (PPI)

Esophagitis
- Esophageal inflammation
- Aim to heal inflammation; proton pump inhibitor indefinitely or surgical fundoplication

Up to 25% of patients with Barrett’s esophagus do not report symptoms of GERD

Updated Guidelines 2008 for the Diagnosis, Surveillance, and Therapy of Barrett’s Esophagus
- Screening of the general population is not recommended and needs to be individualized based on risk factors. Role of esophageal capsule endoscopy for screening is currently under investigation.
- Surveillance interval is based on grade of dysplasia. If no dysplasia confirmed on two endoscopies within a year, then q3yr. For low-grade dysplasia (LGD), repeat endoscopy within 6 mo to ensure there is no high-grade dysplasia (HGD) and if none, then q6yr until no dysplasia on two consecutive endoscopies. If HGD, repeat endoscopy within 3 mo to ensure there is no adenocarcinoma and recommend intervention (endoscopic resection) or intensive surveillance (endoscopy q3mo).
- Diagnosis using alternative imaging techniques (fiberoptic, chromoendoscopy) and biomarkers (DNA content abnormalities, loss of heterozygosity or methylation of specific genes) are being investigated but none are currently ready for routine clinical use.
- Treatment of reflux symptoms with PPI decreases the development of dysplasia. Surgery (fundoplication) for patients without major comorbidities and whose reflux symptoms are controlled on PPI has a 20% failure rate at 5 yr and has not shown to decrease progression to adenocarcinoma.
- Prognosis: 5-yr risk of esophageal adenocarcinoma in high-grade dysplasia is >30%.
- Management in high-grade dysplasia, surveillance with intensive biopsy, endoscopic ablation, or esophagectomy produce similar outcomes and thus should be individualized to patient preference and local expertise.
Significance
• rate of malignant transformation is approximately 0.12% per yr for all BE patients prior to dysplasia
• risk of malignant transformation in high-grade dysplasia is significantly higher; studies have reported a 32-59% transformation rate over 5-8 yr of surveillance
• increased gastric acid secretion is more frequently associated with Barrett’s esophagus as opposed to reflux alone

Management
• acid suppressive therapy with high-dose PPI indefinitely (or surgical fundoplication)
• endoscopy every 3 yr if no dysplasia
• high grade dysplasia: regular and frequent surveillance with intensive biopsy, endoscopic ablation/resection, or esophagectomy produce similar outcomes; however, evidence increasingly favoring endoscopic ablation with mucosal resection or radiofrequency ablation
• if low grade dysplasia, both surveillance and endoscopic ablation/resection are satisfactory options

Dysphagia
Definition
• difficulty swallowing, globus sensation

Esophageal Motor Disorders
Symptoms
• dysphagia with solids and liquids
• chest pain (in some disorders)

Diagnosis
• motility study (esophageal manometry)
• barium swallow sometimes helpful

Causes (Table 3)
• idiopathic
• achalasia (painless)
• scleroderma (painless)
• DM
• DES: rare and can be difficult to diagnose due to intermittent presentation
Table 3. Esophageal Motor Disorders

<table>
<thead>
<tr>
<th>Disorder</th>
<th>Achalasia</th>
<th>Scleroderma</th>
<th>Diffuse Esophageal Spasm</th>
</tr>
</thead>
</table>
| **Definition**  | • Failure of smooth muscle relaxation at LES  
• Increased LES pressure  
• Progressive loss of peristaltic function  
See Rheumatology, RH13  
• Systemic disease characterized by vasculopathy and tissue fibrosis (especially skin thickening)  
• Normal peristalsis interspersed with frequent, repetitive, spontaneous, high pressure, non-peristaltic waves (tertiary peristalsis) |
| **Etiology**    | • Usually idiopathic  
• 2° or pseudo-achalasia: e.g. malignancy, Chagas disease (Trypanosoma cruzi)  
• Involves autoimmune, genetic, hormonal, and environmental factors  
• Dysphagia: caused by reflux, dysmotility, or both |
| **Pathophysiology** | • Inflammatory degeneration of Auerbach’s plexus  
• Blood vessel damage  
• Incomplete relaxation of LES with swallowing, aperistalsis  
• Intramural neuronal dysfunction  
• Distal esophageal muscle weakening  
• Aperistalsis and loss of LES tone  
• Reflux  
• Stricture  
• Dysphagia  
• Potential mechanisms include impaired inhibitory innervation to esophageal body, malfunction in endogenous nitric oxide synthesis |
| **Diagnosis**   | • CXR: no air in stomach, dilated esophagus  
• Barium studies: esophagus terminates in narrowing at LES (“bird’s beak”)  
• Endoscopy: rule out malignancy  
• Manometry: definitive diagnosis (signs listed above)  
• Clinical features of scleroderma  
• Manometry: decreased pressure in LES, decreased peristalsis in body of esophagus  
• Barium x-ray: “Corkscrew pattern”  
• Manometry: >30% (but <100%) of esophageal contractions are aperistaltic |
| **Treatment**   | • Dilatation of LES with balloon, ± GERD prophylaxis, 50% good response, can repeat, risk of perforation (5%)  
• Injection of botulinum toxin into LES (temporary)  
• Surgery (myotomy)  
• Medical: aggressive GERD therapy (PPIs bid)  
• Surgery: anti-reflux surgery (gastroplasty, last resort)  
• Reassurance not cardiac pain  
• Medical: nitrates, calcium channel blockers, anticholinergics have variable benefit  
• Surgical: long esophageal myotomy if unresponsive to above treatment (rarely helpful); balloon dilatation |

**Esophageal Diverticula**

**Definition**
- outpouchings of one or more layers of the esophageal tract

**Clinical Features**
- commonly associated with motility disorders
- dysphagia, regurgitation, retrosternal pain, intermittent vomiting, may be asymptomatic

**Classification**
- classified according to location
  - pharyngoesophageal (Zenker’s) diverticulum
    - most frequent form of esophageal diverticulum
    - posterior pharyngeal outpouching most often on the left side, above cricopharyngeal muscle and below the inferior pharyngeal constrictor muscle
    - symptoms: dysphagia, regurgitation of undigested food, halitosis
    - treatment: endoscopic or surgical myotomy of cricopharyngeal muscle ± surgical excision of sac
  - mid-esophageal diverticulum
    - secondary to mediastinal inflammation, motor disorders
    - usually asymptomatic; no treatment required
    - just proximal to LES (pulsatile type)
    - usually associated with motor disorders
    - usually asymptomatic; no treatment required

**Peptic Stricture (from Esophagitis)**
- presents as dysphagia alongside a long history of reflux symptoms, but reflux symptoms may disappear as stricture develops
- diagnosed with endoscopy or barium study if endoscopy contraindicated or unavailable

**Treatment**
- endoscopic dilatation and indefinite PPI
- anti-reflux surgery if above treatment unsuccessful
**Esophageal Carcinoma**

- see [General Surgery, GS14](#)

**Webs and Rings**

- web = partial occlusion (upper esophagus)
- ring = circumferential narrowing (lower esophagus)

**Clinical Features**

- asymptomatic with lumen diameter > 12 mm, provided peristalsis is normal
- dysphagia with large food boluses
- Schatzki ring
  - mucosal ring at squamo-columnar junction above a hiatus hernia
  - causes intermittent dysphagia with solids
  - treatment involves disrupting ring with endoscopic bougie

**Infectious Esophagitis**

**Definition**

- severe mucosal inflammation and ulceration as a result of a viral or a fungal infection

**Risk Factors**

- DM
- chemotherapeutic agents
- immunocompromised states

**Symptoms**

- characteristically odynophagia, less often dysphagia
- diagnosis is via endoscopic visualization and biopsy

**Appearance**

- Candida (most common): whitish-yellow plaques without visible ulceration or inflammation
- Herpes (second most common), CMV: focal ulcers

**Treatment**

- Candida: nystatin swish and swallow, ketoconazole, fluconazole
- Herpes: often self-limiting; acyclovir, valacyclovir, famciclovir
- CMV: IV gancyclovir, famciclovir, or oral valganciclovir

**Stomach and Duodenum**

**Dyspepsia**

**Definition**

- intermittent epigastric discomfort, characteristically develops after eating

**History and Physical**

- history: most important are age, associated symptoms (such as weight loss and vomiting), and drugs (especially NSAIDs)
- physical exam: adenopathy, abdominal mass/organomegaly, Carnett’s sign (if pain is due to abdominal wall muscle problem then the pain will increase during muscle contraction, such as during a sit-up)

**Investigations**

- laboratory: usual (CBC, liver enzymes, glucose, Cr, etc.) plus amylase, albumin
- consider trial of empiric anti-secretory drug therapy, non-invasive testing for *H. pylori* infection, endoscopy, barium radiography
Gastric Acid Secretion

Stomach
- primary function is mechanical grinding of food facilitating early enzymatic digestion into chyme and propulsion into duodenum

Table 4. Cells of the Gastric Mucosa

Gastritis

Definition
- defined histologically: inflammation of the stomach mucosa

Etiology
- some causative agents may play a role in more than one type of gastritis and an individual patient may have histopathological evidence of more than one type of gastritis

Table 5. Updated Sydney Classification of Gastritis

<table>
<thead>
<tr>
<th>Type</th>
<th>Common Etiology</th>

<td>Crohn’s disease, sarcoidosis</td>
</tr>
<tr>
<td>Other infectious gastritides</td>
<td>Bacteria, viruses, fungi, parasite, TB, syphilis</td>
</tr>
</tbody>
</table>

*Most common causes
Clinical Features
- non-erosive gastritis is asymptomatic (except in certain rare causes like Crohn’s disease); difficult to diagnose clinically or endoscopically
- erosive gastritis can cause bleeding (pain only if progresses to ulcers – rare); can be seen endoscopically

Management
- determined by etiology (see \textit{H. pylori}, G13, NSAID, G14 and \textit{Stress-Induced Ulceration}, G14)
- non-pharmacological: avoidance of mucosal irritants such as alcohol, NSAIDs, and foods that trigger symptoms

### Peptic Ulcer Disease

#### Definition
- focal defects in the mucosal that penetrate the muscularis mucosal layer results in scarring (defects superficial to the muscularis mucosa have erosions and no scarring)
- peptic ulcer disease includes defects located in the stomach (gastric ulcers) and duodenum (duodenal ulcers)

#### Etiology

<table>
<thead>
<tr>
<th></th>
<th>Duodenal</th>
<th>Gastric</th>
</tr>
</thead>
<tbody>
<tr>
<td>\textit{H. pylori} infection</td>
<td>90%</td>
<td>60%</td>

<td>Idiopathic</td>
<td>15%</td>
<td>10%</td>
</tr>
</tbody>
</table>

- NSAID negative, \textit{H. pylori} negative ulcers becoming more commonly recognized
- others: CMV, ischemic, idiopathic
- alcohol: damages gastric mucosa but rarely causes ulcers
- peptic ulcer associated with tobacco, cirrhosis of liver, COPD, and chronic renal failure

#### Clinical Features
- dyspepsia: most common presenting symptom
  - only 20% of patients with dyspepsia have ulcers, while most have functional disease
  - may present with complications
    - bleeding 10% (severe if from gastroduodenal artery) (see \textit{Bleeding Peptic Ulcer}, G13)
    - perforation 2% (usually anterior ulcers)
    - gastric outlet obstruction 2%  
    - penetration (posterior) 2%; may also cause pancreatitis
- duodenal ulcers: 6 classical features, but history alone cannot distinguish from functional dyspepsia
  - epigastric pain; may localize to tip of xiphoid
  - burning
  - develops 1-3 h after meals
  - relieved by eating and antacids
  - interrupts sleep
  - periodicity (tends to occur in clusters over wk with subsequent periods of remission)
- gastric ulcers: more atypical symptoms; a biopsy is necessary to exclude malignancy

#### Investigations
- endoscopy (most accurate)
- upper GI series
- \textit{H. pylori} tests (see Table 7)
- fasting serum gastrin measurement if Zollinger-Ellison (ZE) syndrome suspected

#### Treatment
- specific management depends on etiology (see \textit{H. pylori}, G13, NSAID, G14 and \textit{Stress-Induced Ulceration}, G14)
- eradicate \textit{H. pylori} if present, chief advantage is to lower ulcer recurrence rate
- stop NSAIDs if possible
- start PPI: inhibits parietal cell H⁺/K⁺-ATPase pump which secretes acid
  - heals most ulcers, even if NSAIDs are continued
- other meds (e.g. histamine H₂-antagonists) less effective
- discontinue tobacco
- no diet modifications required but some people have fewer symptoms if they avoid caffeine, alcohol, and spices

### Approach to PUD
- Stop NSAIDs
- Acid neutralization
- \textit{H. pylori} eradication
- Quit smoking

### Cigarette Smoking and PUD
- Increased risk of ulcer
- Increased risk of complications
- Increased chance of death from ulcer
- Impairs healing

### Bleeding Peptic Ulcers: Risk Factors for Increased Mortality
- Co-existent illness
- Hemodynamic instability
- Age >60 yr
- Transfusion required
**Management of Bleeding Peptic Ulcers**

- OGD to explore upper GI tract
- establish risk of rebleeding/continuous bleed
  - clinical risk factors: increased age (>60), bleeding diathesis, history of PUD, comorbid disease, hemodynamically unstable
  - endoscopic signs of recurrent bleeding (active bleeding, visible vessel, clot, red spot) more predictive than clinical risk factors
  - if high risk, consider ICU admission

**Suspected Bleeding Peptic Ulcer**

<table>
<thead>
<tr>
<th>ABCs: assess vitals (BP and HR, orthostatic changes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>CBC, lymes, BUN, Cr, INR, blood type, cross and type</td>
</tr>
<tr>
<td>Resuscitate: crystalloids and blood products if indicated</td>
</tr>
</tbody>
</table>

**Endoscopy**

- Active bleeding or visible vessel
  - High Risk: Hemostasis: clips, thermal coagulation ± epinephrine injection
  - Continue (or start) IV PPI
  - Monitor for re-bleeding in hospital
  - If adherent clot: consider removal

- Flat, pigmented spot or clean base
  - Low Risk: No hemostasis necessary
  - Continue (or start) oral PPI
  - Decreased need for in-hospital monitoring

**Post-Endoscopy**

- Resume clear fluids 6 hours post-endoscopy
- Test for H. pylori
- Counsel re: most likely causes (NSAIDs, anti-platelet agents)
- If re-bleeding: repeat endoscopy with aim of hemostasis
- Consult interventional radiology or surgery if needed

**Figure 6. Approach to management of suspected bleeding peptic ulcer**

Adapted from: Gralnek I, Barkun A, Bardou M. Management of acute bleeding from a peptic ulcer. NEJM 2008;359:928-937

**H. pylori-Induced Peptic Ulceration**

**Pathophysiology**

- *H. pylori*: Gram-negative flagellated rod that resides on but does not invade the gastric mucosa
- acid secreted by parietal cells (stimulated by vagal acetylcholine, gastrin, histamine) necessary for most ulcers
- mucosal defenses moderated by PGE2 and blood flow, mucus, etc.
- theories of how *H. pylori* causes ulcers: none satisfactory, but pattern of colonization correlates with outcome
  - gastritis only in antrum (15% of patients), high gastric acid, associated with peptic ulcer, may progress to gastric metaplasia of duodenum where ulcer forms
  - gastritis throughout stomach (“pangastritis” – 85% of patients), low gastric acid, associated with cancer

**Epidemiology**

- *H. pylori* is found in about 30-40% of all Americans, with rates higher in African-American and Hispanic populations
  - highest prevalence in those raised during 1930s
  - infection most commonly acquired in childhood, presumably by fecal-oral route
  - high prevalence in developing countries, low socioeconomic status (poor sanitation and overcrowding)

**Outcome**

- gastritis (non-erosive) in 100% of patients but asymptomatic
- peptic ulcer in 15% of patients
- gastric malignancy (gastric carcinoma and mucosal associated lymphomatous tissue [MALT] lymphoma in 0.5% of patients)
- most are asymptomatic but still worthwhile eradicating to lower future risk of peptic ulcer/gastric malignancy and prevent spread to others (mostly children <5 yr of age)

**Intragastric pH with Oral vs. Intravenous Bolus plus Infusion Proton-pump Inhibitor Therapy in Patients with Bleeding Ulcers**

Gastroenterology 2008;134:1836-1841

**Study:** Randomized control trial.

**Participants:** Patients presenting with overt bleeding from an ulcer.

**Intervention:** Patients received either IV lansoprazole (90 mg bolus followed by 9 mg/h infusion; n=32) or oral lansoprazole (120 mg bolus followed by 30 mg every 3 h; n=34).

**Primary Outcome:** 24 h pH.

**Results:** Intragastric pH was >6 for >60% of the study period in 22 (68.8%) patients receiving IV and 22 (64.7%) patients receiving oral PPI. At 1 h, mean pHs for IV and oral were 5.3 and 3.3, respectively (difference 2.0; p=0.001). After 1.5 h, there were no differences in mean pH between the groups. Mean pH rose above 6 after 2.3 h of IV PPI and 3.4 h of oral PPI.

**Conclusion:** Frequent oral PPI may be able to replace the currently recommended IV bolus plus infusion PPI therapy in patients with bleeding ulcers. However, IV PPI has a more rapid increase in pH, reaching mean pH of 6 approximately 1 h sooner than oral PPI.

**Treatment: *H. pylori* Eradication**
- triple therapy for 7-14 d (Hp-Pac®): PPI bid (e.g. lansoprazole 30 mg bid) + amoxicillin 1 g bid + clarithromycin 500 mg bid
  - 80% success rate
- quadruple therapy for 10-14 d: PPI bid + bismuth 525 mg qid + tetracycline 500 mg qid + metronidazole 250 mg qid
  - only recommended as first line therapy if resistance to clarithromycin or metronidazole is high, or in patients with recent or repeated exposure to these drugs
  - levofloxacin can replace metronidazole or tetracycline
- sequential therapy
  - days 1-5: PPI bid + amoxicillin 1 g bid
  - days 6-10: PPI bid + clarithromycin 500 mg bid + tinidazole 500 mg bid
- 5-15% of cases are resistant to all known therapies

**NSAID-Induced Ulceration**
- NSAID use causes gastric mucosal petechiae in virtually all, erosions in most, ulcers in some (25%)
  - erosions bleed, but usually only ulcers cause significant clinical problems
- most NSAID ulcers are clinically silent: dyspepsia is as common in patients with ulcers as in patients without ulcers; NSAID-induced ulcers characteristically present with complications (bleeding, perforation, obstruction)
- NSAIDs more commonly cause gastric ulcers than duodenal ulcers
- may exacerbate underlying duodenal ulcer disease

**Pathophysiology**
- direct: erosions/petechiae – are due to local (direct) effect of drug on gastric mucosa
- indirect: systemic NSAID effect (intravenous NSAID causes ulcers, but not erosions), inhibits mucosal cyclooxygenase, leading to decreased synthesis of protective prostaglandins, thus leading to ulcers

**Risk Factors For NSAID Causing Peptic Ulcer**
- previous peptic ulcers/UGIB
- age
- high dose of NSAID/multiple NSAIDs being taken
- concomitant corticosteroid use
- concomitant cardiovascular disease/other significant diseases

**Treatment**
- prophylactic cytoprotective therapy with a PPI is recommended if any of the above risk factors exist concomitantly with ASA/NSAID use
- lower NSAID dose or stop all together and replace with acemetaminophen
- combine NSAID with PPI or misoprostol
- enteric coating of Aspirin® (ECASA) provides minor benefit since this decreases incidence of erosion, not incidence of ulceration

**Stress-Induced Ulceration**

**Definition**
- ulceration or erosion in the upper GI tract of ill patients, usually in ICU
- lesions most commonly in fundus of stomach

**Pathophysiology**
- unclear: likely involves ischemia; may be caused by CNS disease, acid hypersecretion, Cushing ulcers
- physiological stress (e.g. fever, severe illness, complex post-operative course) causes ulcers and erosions
Risk Factors
• mechanical ventilation
• anti-coagulation
• multi-organ failure
• septicemia
• severe surgery/trauma
• CNS injury (“Cushing's ulcers”)
• burns involving more than 35% of body surface

Clinical Features
• UGIB (see Upper Gastrointestinal Bleeding, G25)
• painless

Treatment
• prophylaxis with gastric acid suppressants (H2-blockers or PPI) decreases risk of UGIB, but may increase risk of pneumonia
• treatment same as for bleeding peptic ulcer but often less successful

Gastric Carcinoma
• see General Surgery, GS18

Small and Large Bowel

Classification of Diarrhea

Definition
• clinically: diarrhea defined as stools that are looser and/or more frequent than normal;
  physiologically: 24 h stool weight >200 g (less useful clinically)

Classification
• acute vs. chronic
• small volume (tablespoons of stool; typical of colonic diseases) vs. large volume
  (>1/2 cup stool; typical of small bowel diseases)
• watery (bowel disease) vs. steatorrhea
• secretory (diarrhea persists with fasting) vs. osmotic (diarrhea stops with fasting)

Acute Diarrhea

Definition
• passage of frequent unformed stools for <14 d

Etiology
• most commonly due to infections
• most infections are self-limiting and resolve within 7 d

Risk Factors
• food (seafood, chicken, turkey, eggs, beef)
• medications: antibiotics, laxatives
• others: high risk sexual activity, infectious outbreaks, family history (IBD)

Classification
• broadly divided and classified into inflammatory and non-inflammatory diarrhea
• mechanisms
  ▪ stimulation of intestinal water secretion and inhibition of water absorption (i.e. secretory problem)
  ▪ in inflammatory diarrhea, organisms and cytotoxins invade mucosa, killing mucosal cells and further perpetuating the diarrhea

Table 8. Classification of Acute Diarrhea

<table>

<td>Chief life-threatening problem is electrolyte disturbances/ fluid depletion</td>
</tr>
<tr>
<td>Antibiotics may benefit</td>
<td></td>
<td>Antibiotics unlikely to be helpful</td>
</tr>
</tbody>
</table>

Investigations
- stool cultures/microscopy (C&S/O&P) are required only if diarrhea is inflammatory, severe, or for epidemiological purposes (day care worker, nursing home resident, community outbreaks (e.g. Walkerton), etc.)
  - C&S only tests Campylobacter, Salmonella, Shigella, E. coli
  - other organisms must be ordered separately
- flexible sigmoidoscopy: useful if inflammatory diarrhea suspected
- biopsies are the most useful method of distinguishing idiopathic IBD (Crohn’s disease and ulcerative colitis) from infectious colitis or acute self-limited colitis
- C. difficile toxin: indicated when recent/remote antibiotic use, hospitalization, nursing home, or recent chemotherapy

Treatment
- fluid and electrolyte replacement orally in most cases, intravenous if severe extremes of age/coma
- anti-diarrheals
  - antimitoty agents: diphenoxylate, loperamide (Imodium®); contraindicated in mucosal inflammation
  - side effects: abdominal cramps, toxic megacolon
  - absorbants: kaolin/pectin (Kaopectate®), methylcellulose, activated attapulgite
    - act by absorbing intestinal toxins/micro-organisms, or by coating intestinal mucosa
  - much less effective than antimitoty agents
  - modifiers of fluid transport: bismuth subsalicylate (Pepto-Bismol®) may be helpful
- antibiotics: rarely indicated
  - risks
    - prolonged excretion of enteric pathogen (especially Salmonella)
    - drug side effects (including C. difficile infection)
    - development of resistant strains
    - renal failure/hemolysis (enterohemorrhagic E. coli O157:H7)
  - indications for antimicrobial agents in acute diarrhea
    - sepsis
    - prolonged fever with fecal blood or leukocytes
    - clearly indicated: Shigella, V. cholerae, C. difficile, traveler’s diarrhea (enterotoxigenic E. coli [ETEC]), Giardia, Entamoeba histolytica, Cyclospora
    - much less effective than antimitoty agents
- antimicrobial agents indicate: Salmonella, Campylobacter, Yersinia, non-enterotoxigenic E. coli
- Salmonella: always treat Salmonella typhi (typhoid or enteric fever); treat other Salmonella only if there is underlying immunodeficiency, hemolytic anemia, extremes of age, aneuryms, prosthetic valve grafts/joints, sickle cell disease

Traveler’s Diarrhea
- see Infectious Diseases, ID14

Chronic Diarrhea

Definition
- passage of frequent unformed stool for >14 d
- approach is similar to that of acute diarrhea except that the majority of cases are non-infectious

Etiology/Classification
- see Differential Diagnosis of Common Presenting Complaints, G4

Investigations
- guided by history
- stool analysis for: C. difficile toxin, C&S, O&P ± fecal fat, WBC
- blood for: CBC, electrolytes, CRP, TSH, celiac serology (IgA anti-tTG; ask for serum protein electrophoresis or immunoglobulin quantitation to rule out IgA deficiency which has an increased frequency in celiac disease)
- colonoscopy and ileoscopy with biopsy
- upper GI endoscopy with duodenal biopsy
- wireless small bowel endoscopy capsule (low yield)
- trial of lactose free diet
  - caveat: may delay diagnosis of IBD and celiac disease
Maldigestion and Malabsorption

**Definition**
- *maldigestion*: inability to break down large molecules in the lumen of the intestine into their component small molecules
- *malabsorption*: inability to transport molecules across the intestinal mucosa into circulation
- *malassimilation*: encompasses both maldigestion and malabsorption

**Etiology**
- *maldigestion*
  - inadequate mixing of food with enzymes (e.g. post-gastrectomy)
  - pancreatic exocrine deficiency
  - primary diseases of the pancreas (e.g. cystic fibrosis, pancreatitis, cancer)
  - bile salt deficiency
    - terminal ileal disease (impair recycling), bacterial overgrowth (deconjugation of bile salts), rarely liver disease (cholestatic)
  - specific enzyme deficiencies (e.g. lactase)
- *malabsorption*
  - inadequate absorptive surface
  - infections/infestations (e.g. Whipple’s disease, Giardia)
  - immunologic or allergic injury (e.g. celiac disease)
  - infiltration (e.g. lymphoma, amyloidosis)
  - fibrosis (e.g. systemic sclerosis, radiation enteritis)
  - bowel resection (length, site, and location are important)
  - extensive Crohn's disease
  - drug-induced
    - cholestyramine, ethanol, neomycin, tetracycline, and other antibiotics
  - endocrine
    - DM (complex pathogenesis)

**Clinical Features**
- symptoms usually vague unless disease is severe
- weight loss, diarrhea, steatorrhea, weakness, fatigue
- manifestations of malabsorption/deficiency

</tbody>
</table>

* Calcium malabsorption more commonly causes decreased bone density rather than hypocalcemia because serum calcium levels are protected by leaching calcium from the bone.
**Investigations**

- transglutaminase serology/protein electrophoresis and abdominal imaging are most useful because celiac disease and chronic pancreatitis are the two most common causes of steatorrhea
- 72 h stool collection (weight, fat content) documents steatorrhea (gold standard)
- serum carotene, folate, Ca\(^{2+}\), Mg\(^{2+}\), vitamin B\(_{12}\), albumin, ferritin, serum iron solution, INR/PTT
- stool fat globules on fecal smear stained with Sudan (rarely used)
- other tests specific for etiology (e.g. CT scan/MRI to visualize pancreas)
- trial of therapy with pancreatic enzymes

**Treatment**

- dependent on underlying etiology

---

### Celiac Disease (Gluten Enteropathy/Sprue)

**Definition**

- abnormal small intestine mucosa due to intestinal reaction to gliadin, a component of gluten found in cereal grains

**Etiology**

- only autoimmune disease in which antigen (a peptide in α-gliadin) is recognized
- associated with other autoimmune diseases, especially thyroid disease
- gluten, a protein in cereal grains, broken down to gliadin, is toxic factor
- HLA-DQ2 (chromosome 6) found in 80-90% of patients compared with 20% in general population; also associated with HLA-DQ8

**Epidemiology**

- more common in women
- family history: 15% of first-degree relatives
- may present any time from infancy (when cereals introduced) to elderly
- peak presentation in infancy

**Clinical Features**

- classically: diarrhea, weight loss, anemia, symptoms of vitamin/mineral deficiency, failure to thrive; now more commonly bloating, gas, iron deficiency
- improves with gluten-free diet, deteriorates when gluten reintroduced
- disease is usually most severe in proximal bowel
  - thus iron, calcium, and folic acid deficiency more common than vitamin B\(_{12}\) deficiency
- gluten enteropathy may be associated with dermatitis herpetiformis skin eruption, epilepsy, myopathy, depression, paranoia, infertility, bone fractures/metabolic bone disease

**Investigations**

- small bowel mucosal biopsy (usually duodenum) is diagnostic with:
  - villous atrophy and crypt hyperplasia
  - increased number of plasma cells and lymphocytes in lamina propria
  - increased intraepithelial lymphocytes
  - villous atrophy also seen in small bowel overgrowth, Crohn's, lymphoma, *Giardia*, HIV
- consider CT enterography to visualize small bowel to rule out lymphoma
- evidence of malabsorption (localized or generalized)
  - steatorrhea
  - low levels of ferritin/iron saturation, Ca\(^{2+}\), Fe, albumin, cholesterol, carotene, B\(_{12}\) absorption
- improvement with a gluten-free diet; should not be started before anti-tTG and biopsy
- serological tests
  - serum anti-tTG antibody, IgA, is 90-98% sensitive, 94-97% specific
  - IgA deficient patients have false-negative anti-tTG
  - thus measure serum IgA concomitantly (via serum protein electrophoresis)
- fecal fat >7%

**Treatment**

- dietary counseling
  - gluten free diet: avoid barley, rye, wheat
  - oats allowed if not contaminated by other grains
  - rice and corn flour are acceptable
  - iron, folate supplementation (with supplementation of other vitamins as needed)
- if poor response to diet change, consider
  - alternate diagnosis
  - non-adherence to gluten-free diet
  - concurrent disease (e.g. microscopic colitis, pancreatic insufficiency)
- development of intestinal (enteropathy-associated T-cell) lymphoma (abdominal pain, weight loss, palpable mass)
- development of diffuse intestinal ulceration, characterized by aberrant intraepithelial T-cell population (precursor to lymphoma)

**Prognosis**
- associated with increased risk of lymphoma, carcinoma (e.g. small bowel and colon)
- risk of malignancy may be lowered by dietary gluten restriction

## Inflammatory Bowel Disease

### Definition
- Crohn's disease (CD), ulcerative colitis (UC), indeterminate colitis or IBD-unclassified (IBDU)

### Pathophysiology
- poorly understood
- sustained response of the immune system, perhaps to enteric flora in a genetically predisposed individual
- current hypothesis: lack of appropriate down-regulation of immune responsiveness

### Genetics
- increased risk of both UC and CD in relatives of patients with either disease, especially siblings, early onset disease
- familial risk greater if proband has CD rather than UC
- likely polygenomic pattern: 9 gene loci are associated
- CARD15/NOD2 gene mutation associated with CD (relative risk in heterozygote is 3, in homozygote is 40), especially Ashkenazi Jews, early onset disease, ileal involvement, fistulizing and stenotic disease
- CARD15 gene product modulates NFκB, which is required for the innate immune response to microbial pathogens, best expressed in monocytes-macrophages

### Clinical Features

Crohn’s Disease

Definition
- chronic transmural inflammatory disorder potentially affecting the entire gut from mouth to perianal region (“gum to bum”)

Epidemiology
- incidence 1-6/100,000; prevalence 10-100/100,000
- bimodal: onset before 30 yr, second smaller peak age 60; M=F
- incidence of Crohn’s increasing (relative to UC) especially in young females
- more common in Caucasians, Ashkenazi Jews
  - risk in Asians increases with move to Western countries
- smoking incidence in Crohn’s patients is higher than general population

Pathology
- most common location: ileum + ascending colon
- linear ulcers leading to mucosal islands and “cobblestone” appearance
- granulomas are found in 50% of surgical specimens, 15% of mucosal biopsies

Clinical Features
- natural history unpredictable; young age, perianal disease, and need for corticosteroids have been associated with poor prognosis, but associations are not strong enough to guide clinical decisions
- most often presents as recurrent episodes of abdominal cramps, diarrhea, and weight loss
- ileitis may present with post-prandial pain, vomiting, RLQ mass; mimics acute appendicitis
- extra-intestinal manifestations are more common with colonic involvement
- fistulae, fissures, abscesses are common
- deep fissures with risk of perforation into contiguous viscera (leads to fistulae and abscesses)
- enteric fistulae may communicate with skin, bladder, vagina, and other parts of bowel

Investigations
- colonoscopy with biopsy to visualize (less often gastroscopy)
- CT/MR enterography to visualize small bowel
- CRP elevated in most new cases, useful to monitor treatment response
- bacterial cultures, O&P, C. difficile toxin to exclude other causes of inflammatory diarrhea

Figure 7. Traditional graded approach to induction therapy in Crohn’s disease

Note: Starting with immunosuppressives plus immunomodulators (“bottom-up approach”) increasingly being used (Lancet 2008;371:660-667). Combination of azathioprine and infliximab has the highest remission rate yet described with medical treatment (NEJM 2010;362:1383-1395).
Management (see Figure 7)

<tr>
<td></td>
<td>Enteral diets may aid in remission</td>
</tr>
<tr>
<td></td>
<td>No evidence for any non-enteral diet changing the natural history of Crohn’s disease, but may affect symptoms</td>
</tr>
<tr>
<td></td>
<td>Those with extensive small bowel involvement or extensive resection require electrolyte, mineral, and vitamin supplements (vit D, Ca²⁺, Mg²⁺, zinc, Fe, B₁₂)</td>
</tr>
<tr>
<td>Antidiarrheal Agents*</td>
<td>Loperamide (Imodium®) &gt; diphenoxylate (Lomotil®) &gt; codeine (cheap but addictive)</td>
</tr>
<tr>
<td></td>
<td>All work by decreasing small bowel motility</td>
</tr>
<tr>
<td></td>
<td>CAUTION if colitis is severe (risk of precipitating toxic megacolon), therefore avoid during flare-ups</td>
</tr>
<tr>
<td>5-ASA</td>
<td>Efficacy controversial: most evidence for mild colonic disease</td>
</tr>
<tr>
<td></td>
<td>Sulfasalazine (Salazopyrin®): 5-ASA bound to sulfapyridine</td>
</tr>
<tr>
<td></td>
<td>Hydrolysis by intestinal bacteria releases 5-ASA (active component)</td>
</tr>
<tr>
<td></td>
<td>Dose-dependent efficacy</td>
</tr>
<tr>
<td></td>
<td>Mesalamine (Pentasa®): coated 5-ASA releases 5-ASA in the ileum and colon</td>
</tr>
<tr>
<td>Antibiotics</td>
<td>e.g. metronidazole (20 mg/kg/d, bid or tid dosing) or ciprofloxacin</td>
</tr>
<tr>
<td></td>
<td>Best described for perianal Crohn’s, although characteristically relapse when discontinued</td>
</tr>
<tr>
<td>Corticosteroids</td>
<td>Prednisone: starting dose 40 mg OD for acute exacerbations; IV methylprednisolone if severe</td>
</tr>
<tr>
<td></td>
<td>No proven role for steroids in maintaining remissions; masks intra-abdominal sepsis</td>
</tr>
<tr>
<td>Immunosuppressives</td>
<td>6-mercaptopurine (6-MP), azathioprine (Imuran®); methotrexate (used less often)</td>
</tr>
<tr>
<td></td>
<td>More often used to maintain remission than to treat active inflammation</td>
</tr>
<tr>
<td></td>
<td>Most commonly used as steroid-sparing agents</td>
</tr>
<tr>
<td></td>
<td>i.e. to lower risk of relapse as corticosteroids are withdrawn</td>
</tr>
<tr>
<td></td>
<td>May require ≥3 mo to have beneficial effect; usually continued for several years</td>
</tr>
<tr>
<td></td>
<td>May help to heal fistulae, decrease disease activity</td>
</tr>
<tr>
<td></td>
<td>Side effects: vomiting, pancreatitis, bone marrow suppression, increased risk of malignancy</td>
</tr>
<tr>
<td>Biologics</td>
<td>Infliximab IV (Remicade®) or adalimumab SC (Humira®): both = antibody to TNF-α</td>
</tr>
<tr>
<td></td>
<td>Proven effective for treatment of fistulae and patients with medically refractory CD</td>
</tr>
<tr>
<td></td>
<td>First-line immunosuppressive therapy with infliximab + azathioprine more effective than using either alone</td>
</tr>
<tr>
<td>Surgical/Experimental</td>
<td>Surgical treatment (see General Surgery, GS30)</td>
</tr>
<tr>
<td></td>
<td>Surgery generally reserved for complications such as fistulae, obstruction, abscess, perforation, bleeding, and for medically refractory disease</td>
</tr>
<tr>
<td></td>
<td>If &lt;50% or &lt;200 cm of functional small intestine, risk of short bowel syndrome</td>
</tr>
<tr>
<td></td>
<td>At least 50% clinical recurrence within 5 yr; 85%-within 15 yr; endoscopic recurrence rate even higher</td>
</tr>
<tr>
<td></td>
<td>40% likelihood of second bowel resection, 30% likelihood of third bowel resection</td>
</tr>
<tr>
<td></td>
<td>Complications of ileal resection:</td>
</tr>
<tr>
<td></td>
<td>&lt;100 cm resected → watery diarrhea or cholorrhea (impair bile salt absorption)</td>
</tr>
<tr>
<td></td>
<td>Treatment: cholestyramine or anti-diarrheals e.g. loperamide</td>
</tr>
<tr>
<td></td>
<td>&gt;100 cm resected → steatorrhea (reduced mucosal surface area, bile salt deficiency)</td>
</tr>
<tr>
<td></td>
<td>Treatment: fat restriction, medium chain triglycerides</td>
</tr>
</tbody>
</table>

*Cholestyramine: a bile-salt binding resin; for watery diarrhea with <100 cm of terminal ileum diseased or resected; however, non-specific anti-diarrheals are more convenient and often more potent.

Prognosis

- highly variable course
- 10% disabled by the disease eventually, spontaneous remission also described
- increased mortality, especially with more proximal disease, greatest in the first 4-5 yr
- complications include:
  - intestinal obstruction/perforation
  - fistula formation
  - malignancy (lower risk compared to UC)
- surveillance colonoscopy same as ulcerative colitis (see Ulcerative Colitis, G22) if more than 1/3 of colon involved

Biological Therapies for Inflammatory Bowel Diseases

- Anti-TNF Agents: infliximab, adalimumab, certolizumab: Effective in CD, less effective for UC. Increase mucosal healing, decrease need for hospitalizations and surgeries, and can induce steroid-free remission. At least 10% of patients annually develop intolerance and/or a loss of response.
- Selective Anti-Adhesion Molecules
  - Infliximab: Increases response and remission rates, circulating leukocytes, and steroid-sparing capacity in CD. Progressive multifocal leukoencephalopathy is a rare adverse event.
- Promising New BT: Anti-Interleukin-12
  - Interleukin-23 p40 target factors more often associated with CD, while anti-IFN-α antibodies may treat CD and UC.
- BT Without Established Efficacy: Recombinant human cytokines, blockade of T-cell activation (fotolizumab and basiliximab) and stimulators of the innate immune system.

Conclusion: Anti-TNF agents are effective treatments for IBD. There is a need to develop salvage biological therapies for patients who do not respond to a first biological drug. BT’s have a safety risk, so their place in treatment algorithms must be defined carefully.

Characteristic more than 1 yr between onset of symptoms and diagnosis of Crohn’s disease
Ulcerative Colitis

Definition
- inflammatory disease affecting colonic mucosa anywhere from rectum (always involved) to cecum

Epidemiology
- incidence 2-10/100,000; prevalence 35-100/100,000 (more common than Crohn's)
- 2/3 onset by age 30 (with second peak after 50); M=F
- small hereditary contribution (15% of cases have 1st degree relative with disease)
- risk is less in smokers
- inflammation limited to rectum or left colon is more common than pancolitis

Pathology
- disease can involve any portion of lower bowel ranging from rectum only (proctitis) to entire colon (pancolitis)
- inflammation is diffuse, continuous and confined to mucosa

Clinical Features
- rectal bleeding is the hallmark feature, however diarrhea may be present if more than the rectum is involved
  ▪ can also have abdominal cramps/pain, especially with defecation
- severity of colonic inflammation correlates with symptoms (stool volume, amount of blood in stool)
- tenesmus, urgency, incontinence
- systemic symptoms: fever, anorexia, weight loss, fatigue in severe cases
- extra-intestinal manifestations (see Table 11)
- characteristic exacerbations and remissions; 5% of cases are fulminant

Investigations
- sigmoidoscopy with mucosal biopsy (to exclude self-limited colitis) without bowel prep often sufficient for diagnosis
- colonoscopy helpful to determine extent of disease; contraindicated in severe exacerbation
- CT colonography (formerly barium enema) if colonoscopy cannot be done; contraindicated in severe disease
- stool culture, microscopy, C. difficile toxin assay necessary to exclude infection
- no single confirmatory test

Management
- mainstays of treatment: 5-ASA (mesalamine) derivatives and corticosteroids, with azathioprine used in steroid-dependent or resistant cases
- diet of little value in decreasing inflammation but may alleviate symptoms
- antidiarrheal medications generally not indicated in UC
- 5-ASA
  ▪ topical (suppository or enema): very effective for distal disease (distal to splenic flexure), preferable to corticosteroids
  ▪ oral: effective for mild to moderate, but not severe colitis (4 g/d)
  ▪ e.g. sulfasalazine 3-4 g/d, mesalamine 4 g/d
  ▪ commonly used in maintaining remission (decreases yearly relapse rate from 60% to 15%)
  ▪ may decrease rate of colorectal cancer
- corticosteroids
  ▪ to remit acute disease, especially if severe or first attack; may need maximum dose IV steroids initially (e.g. methylprednisolone 30 mg IV q12h)
  ▪ limited role as maintenance therapy
  ▪ use suppositories for proctitis, enemas for proctosigmoiditis
  ▪ topical steroids (e.g. hydrocortisone foam, budesonide enemas) for inflammation distal to splenic flexure
- immunosuppressants (steroid-sparing)
  ▪ if severe UC is refractory to steroid therapy, consider adding IV cyclosporine or IV infliximab within 3-5 d of recognition of need for salvage – rapidly effective, but helpful only in a minority of patients
  ▪ azathioprine: too slow to rapidly resolve acute relapse
  ▪ most commonly used to induce and maintain remission as corticosteroids withdrawn
- surgical treatment
  ▪ early in severe UC, especially fulminant cases and toxic megacolon – consider operation if no response after 3-5 d of corticosteroids, or after 4-7 d of immunosuppressive medical therapy
  ▪ aim for cure with colectomy; bowel continuity can be restored with ileal pouch-anal anastomosis (IPAA)
  ▪ indications: failure of adequate medical therapy, toxic megacolon, uncontrollable bleeding, pre-cancerous changes detected either by endoscopy or endoscopic biopsies (dysplasia), inability to taper corticosteroids, overt malignancy

In UC, non-bloody diarrhea is frequently the initial presentation; eventually progressing to bloody diarrhea
Complications
- similar to CD, except
  - more liver problems (especially PSC in men)
  - greater risk of colorectal cancer
    - risk increases with duration and extent of disease (5% at 10 yr, 15% at 20 yr for pancolitis; overall relative risk is 8%)
    - risk also increases with active mucosal inflammation and sclerosing cholangitis
    - thus, regular colonoscopy and biopsy in pancolitis of ≥8 yr is indicated
  - toxic megacolon (transverse colon diameter >6 cm on abdominal x-ray) with immediate danger of perforation (see General Surgery, GS26)

Prognosis
- chronic relapsing pattern in most patients
- 10-15% chronic continuous pattern
- >1 attack in almost all patients
- more colonic involvement in the 1st yr correlates with increased severity of attacks and increased colectomy rate
  - colectomy rate = 1% for all patients after the 1st yr; 20-25% eventually undergo colectomy
- normal life expectancy
- if proctitis only, usually benign course

Irritable Bowel Syndrome

Definition
- a form of functional bowel disease, more than just a label for GI symptoms unexplained after investigations

Epidemiology
- 20% of North Americans
- onset of symptoms usually in young adulthood
- F>M
**Pathophysiology**

- associated with either abnormal perception of intestinal activity or abnormal intestinal motility
- abnormal motility: multiple abnormalities described; unclear if associations or if causative
- psychological: stress may increase IBS symptoms but does not cause IBS

**Diagnosis**

**Table 13. Rome III Criteria for Diagnosing Irritable Bowel Syndrome**

<table>
<thead>
<tr>
<th>IBS Rome III Criteria</th>
</tr>
</thead>
<tbody>
<tr>
<td>• ≥12 wk in the past 12 mo of abdominal discomfort or pain that has 2 out of 3 features:</td>
</tr>
<tr>
<td>• Relieved with defecation</td>
</tr>
<tr>
<td>• Associated with a change in frequency of stool</td>
</tr>
<tr>
<td>• Associated with a change in consistency of stool</td>
</tr>
<tr>
<td>• The following are supportive, but not essential to the diagnosis:</td>
</tr>
<tr>
<td>• Abnormal stool frequency (&gt;3/d or &lt;3/wk)</td>
</tr>
<tr>
<td>• Abnormal stool form (lumpy/hard/loose/watery) &gt;1/4 of defecations</td>
</tr>
<tr>
<td>• Abnormal stool passage (straining, urgency, feeling of incomplete evacuation) &gt;1/4 of defecations</td>
</tr>
<tr>
<td>• Passage of mucus &gt;1/4 of defecations</td>
</tr>
<tr>
<td>• Bloating</td>
</tr>
</tbody>
</table>

**Diagnosis of IBS Less Likely in Presence of “Red Flag” Features**

| Weight loss | Anemia |
| Fever | Blood or pus in stool |
| Nighturnal defecation | Abnormal gross findings on flexible sigmoidoscopy |

**Investigations**

- if history consistent with Rome III criteria, no alarm symptoms, and no family history of IBD or colorectal cancer, limited investigations required
- aim is to rule out diseases which mimic IBS
- CBC, TSH, albumin, CRP, tTG serology with protein electrophoresis
- stool for C&S, O&P, fecal fat if diarrhea present
- consider sigmoidoscopy

**Management**

- reassurance, explanation, support, aim for realistic goals
- relaxation therapy, biofeedback, hypnosis, stress reduction
- no therapeutic agent consistently effective, pain most difficult to control
- symptom-guided treatment
  - pain predominant
    - antispasmodic medication before meals (e.g. hyoscine, pinaverium, trimebutine)
    - increase dietary fiber (bran or psyllium)
  - diarrhoea predominant (IBS-D)
    - increase dietary fiber (bran or psyllium) to increase stool consistency
    - loperamide (Imodium*)
    - diphenoxylate (Lomotil*)
  - constipation predominant (IBS-C)
    - exercise and increase fiber in diet
    - osmotic or other laxatives
  - mixed (alternating constipation and diarrhea) (IBS-M)

**Prognosis**

- 80% improve over time
- most have intermittent episodes
- normal life expectancy

**Constipation**

**Definition**

- passage of infrequent or hard stools with straining (stool water <50 mL/d); bowel frequency <3 times/wk

**Epidemiology**

- increasing prevalence with age; F>M
- rare in Africa and India where stool weight is 3-4x greater than in Western countries
Etiology
• If constipation is the only presenting symptom, underlying disease is only rarely found. Only test indicated in this situation is a complete blood count (2013 recommendation of American Gastroenterology Association), but consider TSH, calcium, and glucose
• Most common: idiopathic attributed to colon dysmotility but this is difficult to measure
• Organic causes
  • Medication side effects (narcotics, antidepressants) are the most common
  • Intestinal obstruction, left sided colon cancer (consider in older patients), and fecal impaction
  • Metabolic
    • DM
    • Hypothyroidism
    • Hypercalcemia, hypokalemia, uremia
  • Neurological
    • Intestinal pseudo-obstruction
    • Parkinson’s disease
    • MS
    • Collagen vascular disease (e.g. scleroderma)
    • Painful anal conditions (e.g. fissures)

Clinical Presentation
• Overlaps with irritable bowel syndrome
• Stool firm, difficult to expel, passed with straining, abdominal pain relieved by defecation, flatulence, overflow diarrhea, tenesmus, abdominal distension, infrequent BMs (<3/wk)

Investigations
• Colon visualization if concomitant symptoms such as rectal bleeding, weight loss, or anemia (colonoscopy, CT colonography)
• If refractory to treatment, consider classification based on colon transit time; can measure colon transit time with radioopaque markers that are ingested and followed with a series of plain film abdominal x-rays (normal: 70 h)
  1. Normal = misperception of normal defecation (IBS)
  2. Prolonged throughout = “colonic inertia” (infrequent bowel movements with gas/bloating, tends to occur in youth)
  3. Outlet obstruction = inability to coordinate pelvic floor muscles to empty rectum, straining, stool in rectum on digital exam, tends to occur in old age
• Combination of (2) and (3) common

Treatment (in order of increasing potency)
• Dietary fiber
  • Useful if mild or moderate constipation, but not if severe
  • Aim for 30 g daily, increase dose slowly
• Surface-acting (soften and lubricate)
  • Docusate salts, mineral oils
• Osmotic agents (effective in 2-3 d)
  • Lactulose, sorbitol, magnesium salts (e.g. magnesium hydroxide, i.e. milk of magnesia), lactitol, polyethylene glycol 3350
• Cathartics/stimulants (effective in 24 h)
  • Castor oil, senna (avoid prolonged use to prevent melanosis coli), bisacodyl
• Enemas and suppositories (e.g. saline enema, phosphate enema, glycerin suppository, bisacodyl suppository)
• Prokinetic agents (prucalopride)

Upper Gastrointestinal Bleeding

Definition
• Bleeding proximal to the ligament of Treitz (75% of GI bleeds)
  • Ligament of Treitz: suspensory ligament where fourth portion of the duodenum transitions to jejunum

Etiology
• Above the GE junction
  • Epistaxis
  • Esophageal varices (10-30%)
  • Esophagitis
  • Esophageal cancer
  • Mallory-Weiss tear (10%)
• Stomach
  • Gastric ulcer (20%) (see Peptic Ulcer Disease, G12)
  • Gastritis (e.g. from alcohol or post-surgery) (20%)
  • Gastric cancer
  • Gastric antral vascular ectasia (rare, associated with cirrhosis and CTD)
  • Dieulafoy’s lesion (very rare)
• duodenum
  • ulcer in bulb (25%)
  • aortoenteric fistula: usually only if previous aortic graft (see sidebar, G25)
  • coagulopathy (drugs, renal disease, liver disease)
  • vascular malformation (Dieulafoy’s lesion, AVM)

Clinical Features
• in order of decreasing severity of the bleed: hematochezia > hematemesis > coffee ground emesis > melena > occult blood in stool

Management (initial)
• stabilize patient (1-2 large bore IVs, IV fluids, monitor)
• send blood for CBC, cross and type, platelets, PT, PTT, electrolytes, BUN, Cr, LFTs
• keep NPO
• consider NG tube to determine upper vs. lower GI bleeding in some cases
• endoscopy (OGD): establish bleeding site + treat lesion
  • if bleeding peptic ulcer: most commonly used method of controlling bleeding is injection of epinephrine around bleeding point + thermal hemostasis (bipolar electrocoagulation or heater probe); less often thermal hemostasis may be used alone, but injection alone not recommended
• IV PPI: decrease risk of rebleed if endoscopic predictors of rebleeding seen (see prognosis section)
• given to stabilize clot, not to accelerate ulcer healing
• if given before endoscopy, decreases need for endoscopic therapeutic intervention
• for variceal bleeds, octreotide 50 µg loading dose followed by constant infusion of 50 µg/h
• consider IV erythromycin (or metoclopramide) to accelerate gastric emptying prior to gastroscopy to remove clots from stomach

Prognosis
• 80% stop spontaneously
• peptic ulcer bleeding: low mortality (2%) unless rebleeding occurs (25% of patients, 10% mortality)
• endoscopic predictors of rebleeding: spurt or ooze, visible vessel, fibrin clot
• can send home if clinically stable, bleed is minor, no comorbidities, endoscopy shows clean ulcer with no predictors of rebleeding
• H₂-antagonists have little impact on rebleeding rates and need for surgery
• esophageal varices have a high rebleeding rate (55%) and mortality (29%)

Approach to Iron Deficiency Anemia

![Image of Approach to Iron Deficiency Anemia]

- Overt GI bleeding (hematochezia, melena)
  - Yes: treat
  - No: wireless endoscopy capsule/double balloon endoscopy

- Source of bleeding found?
  - Yes: follow
  - No: proceed as if overt GI bleeding present

- Has the anemia resolved?
  - Yes: follow
  - No: proceed as if overt GI bleeding present

- Rule out non-GI sources of bleeding (e.g. menorrhagia, hemolytic anemia)

* Wireless endoscopy capsule results help double balloon endoscopy localize source of bleeding
* Angiography if overt bleeding hemodynamically significant, estimated >0.5 cc/min
* CT enterography if wireless endoscopy capsule/double balloon endoscopy not available

Figure 9. Approach to iron deficiency anemia

Esophageal Varices

Etiology
• almost always due to portal HTN
• often accompanied by varices in stomach

Clinical Features
• characteristically massive upper GI bleeding

Prognosis
• risk of bleeding: 30% in 1st yr
• risk of rebleeding: 50-70% (20% mortality at 6 wk)
In a prospective study of upper GI tract bleeding, mortality, recurrent bleeding, and adverse events were lower when transfusions were given only when the hemoglobin concentration fell below 7.0 g/dL, compared to transfusions given when the hemoglobin fell below 9.0 g/dL. The benefit was most marked in variceal bleeding with Child-Pugh Class A or B cirrhosis (see below under cirrhosis), but also seen in peptic ulcer. Exclusion criteria included exsanguinating bleeding, acute coronary syndrome, and stroke. N Engl J Med 2013;368:11-21.

**Mallory-Weiss Tear**

**Definition**
- longitudinal laceration in gastric mucosa on lesser curvature near GE junction (20% straddle junction, 5% in distal esophagus)

**Etiology**
- due to rapid increases in gastric pressure from retching/vomiting against a closed glottis
- hiatus hernia usually present

**Clinical Features**
- hematemesis ± melena, classically following an episode of retching without blood
- can lead to fatal hematemesis

**Management**
- 90% stop spontaneously
- if persistent: endoscopy with epinephrine injection ± clips or surgical repair

**Lower Gastrointestinal Bleeding**

**Definition**
- bleed distal to ligament of Treitz

**Etiology**
- if blood per rectum with hemodynamic instability, rule out upper GI source
- diverticular (60% from right colon)
- vascular
  - angiodysplasia
  - anorectal (hemorrhoids, fissures)
- neoplasm
  - cancer
  - polyps
- inflammation
  - colitis (ulcerative, infectious, radiation, ischemic)
  - post-polypectomy

**Clinical Features**
- hematochezia (see Figure 11)
- anemia
- occult blood in stool
- rarely melena

**Management**
- treat underlying cause
Figure 11. Approach to hematochezia

Colorectal Carcinoma

Benign Anorectal Disease
- see General Surgery, GS38

Liver

Investigations of Hepatobiliary Disease

A. TEST OF LIVER FUNCTION

Prothrombin Time (PT or INR)
- a marker of hepatic protein synthesis
- increased by
  - impaired hepatic protein synthesis (>80%) (including all coagulation factors except VIII) i.e. hepatocellular dysfunction
  - vitamin K deficiency
  - vitamin K administration promptly corrects PT in vitamin K deficiency (malnutrition, malabsorption, etc.) but not in hepatocellular dysfunction; thus in the absence of vitamin K deficiency, INR/PT is a reliable index of hepatocellular dysfunction

Serum Albumin Level
- a marker of hepatic protein synthesis; must exclude malnutrition, renal or GI losses, and significant inflammatory or malignant illness of any organ system

Serum Bilirubin
- marker of hepatic excretion; transport from hepatocyte to bile
- canaliculus breakdown product of hemoglobin; metabolized in the reticuloendothelial system of liver, transported through biliary system, excreted via gut
- direct bilirubin = conjugated; indirect = unconjugated bilirubin
- liver dysfunction causes hyperbilirubinemia (elevated direct bilirubin) since conjugation preserved even in end stage liver failure

Serum transaminases >1000 due to
- Viral hepatitis
- Drugs
- Autoimmune hepatitis
- Hepatic ischemia
- Less often, common bile duct stone

ALT > AST = most causes of hepatitis
AST > ALT = alcoholic liver disease or other causes of hepatitis that have progressed to advanced cirrhosis

All clotting factors except factor VIII and von Willebrand factor are exclusively synthesized in the liver

For SLOW bleeding (<0.5 ml/min): radionucleotide Tc-99m-tagged RBC scan
- For RAPID bleeding (>0.5 ml/min): angiography ± embolization
Table 14. Test of Liver Function

<table>
<thead>
<tr>

<td>Liver dysfunction</td>
<td>Conjugation is preserved even in end stage liver failure, thus increased direct bilirubin indicates liver dysfunction</td>
</tr>
</tbody>
</table>

B. TESTS OF LIVER INJURY

- disproportionately increased AST or ALT = hepatocellular damage
  - ALT more specific to liver; AST from multiple sources (especially muscle)
  - elevation of both highly suggestive of liver injury
  - most common cause of elevated ALT is fatty liver
- disproportionately increased ALP and GGT = cholestasis
  - if ALP is elevated alone, rule out bone disease by fractionating ALP and/or checking GGT
  - if ALP elevation out of proportion to ALT/AST elevation, consider:
    1. obstruction of common bile duct (extraluminal = pancreatic Ca, lymphoma; intraluminal = stones, cholangiocarcinoma, sclerosing cholangitis, hemihelms)
    2. destruction of microscopic ducts (e.g. PBC)
    3. bile acid transporter defects (drugs, intrahepatic cholestasis of pregnancy)
    4. infiltration of the liver (liver metastases, lymphoma, granulomas, amyloid)

Acute Viral Hepatitis (General)

Definition
- viral hepatitis lasting <6 mo

Clinical Features
- most are subclinical
- flu-like prodrome may precede jaundice by 1-2 wk
- N/V, anorexia, fatigue, myalgia, low-grade fever
- arthralgia and urticaria (especially HBV)
- only some progress to icteric (clinical jaundice) phase, lasting days to weeks
- pale stools and dark urine 1-5 d prior to icteric phase
- hepatomegaly and RUQ pain
- splenomegaly and cervical lymphadenopathy (10-20% of cases)

Investigations
- AST and ALT (>10-20x normal in hepatocellular necrosis)
- ALP minimally elevated
- viral serology, particularly the IgM antibody directed to the virus

Treatment
- supportive (hydration, diet)
- indications for hospitalization: encephalopathy, coagulopathy, severe vomiting, hypoglycemia

Prognosis
- poor prognostic indicators: comorbidities, persistently high bilirubin 20 mg/dL, increased INR, decreased albumin, hypoglycemia

Complications
- hepatocellular necrosis: AST, ALT >10-20x normal, ALP and bilirubin minimally increased, increased cholestasis

Hepatitis A Virus

- RNA virus
- fecal-oral transmission, incubation period 4-6 wk
- diagnosed by elevated transaminases, positive anti-HAV IgM
- in children: characteristically asymptomatic
- in adults: fatigue, nausea, arthralgia, fever, jaundice

Alcoholic hepatitis: history of recent alcohol, RUQ abdominal pain, AST/ALT >2, AST usually <200, low grade fever, mildly elevated WBC

Major Sources of ALP
- Hepatobiliary tree
- Bone
- Placenta

DDx for Hepatomegaly
- Congestive (right heart failure, Budd-Chiari syndrome)
- Infiltrative
  - Malignant (primary, secondary, lymphoproliferative, leukemia)
  - Benign (fatty liver, cysts, hemochromatosis, extramedullary hematopoiesis, amyloid)
- Proliferative
  - Infectious (viral, tuberculosis, abscess, echinococcus)
  - Inflammatory (granulomas [sarcoid], histiocytosis X)

DDx for Hepatitis
- Viral infection
- Alcohol
- Drugs
- Immune-mediated
- Toxins

Causes of Elevated Serum Transaminases in Chronic Hepatitis B
- Ongoing immune-mediated liver injury without immune control of HBV
- Reactivation from prior immune control due to lack of adequate immune control
- Seroconversion (HBeAg converting to anti-HBe, spontaneously or with Rx)
- Hepatitis D
- Other liver insult (fatty liver, alcohol, drugs, hepatitis A)
• can cause acute liver failure and subsequent death (<1-5%)
• can relapse, but never becomes chronic

**Hepatitis B Virus**

**Table 15. Hepatitis B Serology**

**Epidemiology**

• 4 phases of chronic hepatitis B: not all will go through all 4 phases, but all will have positive HBsAg
  1. **immune tolerance**: extremely high HBV-DNA (>20,000 IU/mL), HBeAg positive, but normal ALT/AST; due to little immune control and minimal immune-mediated liver damage; characteristic of perinatal infection (or ‘incubation period’ in adult with newly-acquired HBV)
  2. **immune clearance** (or immunoactive): falling but still elevated HBV-DNA levels (>20,000 IU/mL), HBeAg positive; due to immune attack on the virus and immune-mediated liver damage; characterized by progressive disease without treatment and increasing liver fibrosis (sometimes progressing to cirrhosis and/or hepatocellular carcinoma); likely to benefit from treatment
  3. **immune control**: lower HBV-DNA (<20,000 IU/mL), HBeAg negative, anti-HBe positive, ALT/AST normal; due to immune control without immune-mediated liver damage; risk of reactivation to phase 2 (clinically resembles acute hepatitis B), especially with immunosuppression e.g. corticosteroids or chemotherapy
  4. **immune escape** (“core or precore mutant”); elevated HBV-DNA (>2,000 IU/mL), HBeAg negative because of pre-core or core promoter gene mutation, anti-HBe positive, ALT/AST high; characterized by progressive disease without treatment and increasing liver fibrosis (sometimes progressing to cirrhosis and/or hepatocellular carcinoma); likely to benefit from treatment

**Management**

• counseling: 40% of men and 10% of women with perinatal infection will die from HBV-related complications
• prolonged immune-mediated damage leads to higher risk of liver fibrosis
• hepatocellular carcinoma screening with ultrasound ≥6mo, especially if high serum HBV-DNA levels, cirrhosis, men, (age >40 in Asian men, >50 in Asian women, and >20 in African descent)
• consider pharmacological therapy if
  1. HBeAg positive + HBV-DNA >20,000 IU/mL + elevated ALT; or
  2. HBeAg negative + HBV-DNA >2,000 IU/mL + elevated ALT + stage ≥2 fibrosis on liver biopsy
• treat to prevent flare when placed on immunosuppressive therapy such as prednisone
• treatment goal: reduce serum HBV-DNA to undetectable level

**Figure 12. Time course of acute hepatitis B infection**

Without treatment, 8-20% of those with ongoing immunoactive chronic hepatitis can develop cirrhosis within 5 yr. In contrast, those in the immune tolerant phase (with extremely high HBV-DNA levels) are at minimal risk for liver fibrosis as they do not have immune-mediated liver injury.

In acute hepatitis B, HDV co-infection increases severity of hepatitis but does not increase risk of progression to chronic hepatitis. However, in the context of chronic hepatitis B, superinfection with HDV increases progression to cirrhosis.
• treatment options: interferon, tenofovir, entacavir, lamivudine, adefovir
• vaccine against HAV if serology negative (to prevent further liver damage)
• follow blood and sexual precautions

**Hepatitis D**
• defective RNA virus requiring HBsAg for entry into hepatocyte, therefore infects only patients with hepatitis B; causes more aggressive disease than hepatitis B virus alone
• co-infection: acquire HDV and HBV at the same time
  ▪ better prognosis than superinfection (acute HDV infection on pre-existing HBV infection)
• HDV can present as ALF and/or accelerate progression to cirrhosis
• management: low-dose interferon (20% response) and liver transplant for end-stage disease

**Hepatitis C Virus**
• RNA virus
• blood-borne transmission; sexual transmission is “inefficient”
• major risk factor: injection drug use
• other risk factors: blood transfusion received before 1992 (or received in developing world), tattoos, intranasal cocaine use
• clinical manifestation develops 6-8 wk after exposure
  ▪ symptoms mild and vague (fatigue, malaise, nausea) therefore not commonly diagnosed in acute stage

**Diagnosis**
• suspected on basis of elevated ALT/AST and positive serum anti-HCV
• diagnosis established by detectable HCV-RNA in serum
• virus genotype correlates with response to treatment but not prognosis
  ▪ serum HCV-RNA inversely correlates with response to treatment
• normal transaminases can have underlying cirrhosis on biopsy, but otherwise excellent prognosis

**Management**
• blood-borne precautions; vaccinate for hepatitis A and B if serology negative; avoid alcohol
• clearest indication for treatment is in subgroup likely to develop clinically significant liver disease
  ▪ persistently elevated transaminases, liver biopsy shows fibrosis/cirrhosis and at least moderately severe necrosis/inflammation
• indicators of poor response to treatment: cirrhosis, genotype 1, high HCV-RNA, co-infection with HIV, African-American race
• pegylated interferon-α + ribavirin aims to clear HCV infection, but only 50-80% success rate and side effects common (therefore not all patients are treated)
  ▪ sustained virologic response (SVR) = undetectable HCV-RNA 3-6 mo off treatment (which generally means that HCV has been successfully eradicated) = “cure”
  ▪ pegylated interferon-α SC injection weekly and ribavarin PO bid and add protease inhibitor PO (bocepravir or telaprevir) for genotype 1
• length of treatment often determined by rapidity and degree of fall in HCV RNA level
• adverse effects: depression/fatigue, hemolysis, bone marrow suppression (monitor CBC regularly), fevers/myalgia, precipitates autoimmune diseases (rare), skin rashes
• recently introduced protease inhibitors for genotype 1 (most common, least amenable to treatment) have significantly increased sustained remission rate to up to 70%
• interferon-free regimens using combinations (>2) of oral anti-viral drugs have shown high efficacy and will likely be the mainstay of treatment in future years

**Prognosis**
• 80% of acute hepatitis C become chronic (of these 20% evolve to cirrhosis)
• risk of hepatocellular carcinoma increases if cirrhotic
• can cause cryoglobulinemia; associated with membranoproliferative glomerulonephritis, lymphoma

**Risk Factors for Progression**
• EtOH
• HIV co-infection
• Old age at diagnosis

**HCV treatment lowers the risk of hepatocellular carcinoma**

</tbody>
</table>

---

**Autoimmune Chronic Active Hepatitis**

- diagnosis of exclusion: rule out viruses, drugs, metabolic, or genetic causes
- can be severe: 40% mortality at 6 mo without treatment
- extrahepatic manifestations
  - sicca, Raynaud’s, thyroiditis, Sjögren’s, arthralgias
  - hypergammaglobulinemia
    - anti-smooth muscle antibody elevation is most characteristic; also elevations in anti-LKM (liver kidney microsome, especially in children)
    - less specific: elevated ANA, RF
  - can have false positive viral serology (especially anti-HCV)
  - biopsy – perportal (zone 1) and interface inflammation and necrosis
management: corticosteroids (80% respond) ± azathioprine (without this, most will relapse as corticosteroids are withdrawn)

#### Specific Drugs

- **acetaminophen**
  - metabolized by hepatic cytochrome P450 system
  - can cause ALF (transaminases >1,000 U/L followed by jaundice and encephalopathy)
  - requires 10-15 g in healthy, 4-6 g in alcoholics/anticonvulsant users
  - mechanism: high acetaminophen dose saturates glucuronidation and sulfation elimination pathways → reactive metabolite is formed → covalently binds to hepatocyte membrane
  - presentation
    - first 24 h: N/V (usually within 4-12 h of overdose)
    - 24-48 h: asymptomatic, but ongoing hepatic necrosis resulting in increased transaminases
    - >48 h: continued hepatic necrosis possibly complicated with ALF or resolution
    - note: potential delay in presentation in sustained-release products
  - blood levels of acetaminophen correlate with the severity of hepatic injury, particularly if time of ingestion known
  - therapy
    - gastric lavage/emesis (if <2 h after ingestion)
    - oral activated charcoal
    - N-acetylcysteine (NAC, Mucomyst®) can be given PO or IV (most effective within 8-10 h of ingestion, but should be given no matter when time of ingestion)
      - promotes hepatic glutathione regeneration
      - no recorded fatal outcomes if NAC given before increase in transaminases

- **chlorpromazine**: cholestasis in 1% after 4 wk; often with fever, rash, jaundice, pruritus, and eosinophilia

- **INH (isoniazid)**
  - 20% develop elevated transaminases but <1% develop clinically significant disease
  - susceptibility to injury increases with age

- **methotrexate**
  - causes fibrosis/cirrhosis; increased risk in the presence of obesity, DM, alcoholism (i.e. with underlying risk for pre-existing fatty liver)
  - scarring develops without symptoms or changes in liver enzymes, therefore biopsy may be needed in long-term treatment

- **amiodarone**: can cause same histology and clinical outcome as alcoholic hepatitis

- **others**: azoles, statins, methylxanthines, phenytoin, propylthiouracil (PTU), rifampin, sulfonamides, tetracyclines

- **herbs**: chaparral, Chinese herbs (e.g. germander, comfrey, bush tea)

### Wilson’s Disease

**Definition**
- autosomal recessive defect in copper metabolism (gene ATP7B)

**Pathology**
- decreased biliary excretion of copper plus decreased incorporation of copper into ceruloplasmin

**Clinical Manifestations**
- liver: acute hepatitis, acute liver failure, chronic active hepatitis, cirrhosis, low risk of hepatocellular carcinoma
- eyes: Kayser-Fleischer rings (copper deposits in Descemet’s membrane); more common in patients with CNS involvement, present in 50% if only liver involvement
- CNS: basal ganglia (wing flapping tremor, Parkinsonism), cerebellum (dysarthria, dysphagia, incoordination, ataxia), cerebrum (psychosis, affective disorder)
- kidneys: Fanconi’s syndrome (proximal tubule transport defects) and stones

**Clinical Manifestations of Wilson’s Disease**

**ABCD**
- Asterisk
- Basal ganglia degeneration: suspect if parkinsonian features in the young
- Ceruloplasmin ↓
- Cirrhosis
- Corneal deposits (Kayser-Fleischer ring)
- Copper
- Dementia
• blood: intravascular hemolysis; may be initial presentation in fulminant hepatitis
• joints: arthritis, bone demineralization, calcifications

**Investigations**
• suspect if increased liver enzymes with clinical manifestations at young age (<30); especially combination of liver disease with dystonia, psychiatric symptoms
• screening tests
  1. reduced serum ceruloplasmin (<50% of normal)
  2. Kayser-Fleischer rings (usually require slit-lamp examination)
  3. increased urinary copper excretion
• gold standard
  1. increased copper on liver biopsy by quantitative assay
  2. genetic analysis imperfect as many mutations in ATP7B are possible

**Treatment**
• 4 drugs available
  1. penicillamine chelates copper; poorly tolerated
  2. trientine chelates copper
  3. zinc impairs copper excretion in stool/decreases copper absorption from gut
  4. tetrathiomolybdate preferred if neurological involvement
• screen relatives
• liver transplant in severe cases

---

**Hemochromatosis**

**Definition**
• excessive iron storage causing multiorgan system dysfunction (liver, in particular) with total body stores of iron increased to 20–40 g (normal 1 g)

**Pathology**
• primary hemochromatosis
  ▪ primarily due to common recessive gene (HFE, 5%); 1/400 patients are homozygotes
  ▪ results in ongoing gut absorption of iron despite adequate iron stores
• secondary hemochromatosis
  ▪ parenteral iron overload (e.g. transfusions)
  ▪ chronic hemolytic anemia: thalassemia, pyruvate kinase deficiency
  ▪ excessive iron intake

**Clinical Manifestations**
• usually presents with trivial elevation in serum transaminases
• liver: cirrhosis (30%), HCC (200x increased risk) – most common cause of death (1/3 of patients)
• pancreas: DM, chronic pancreatitis
• skin: bronze or gray (due to melanin, not iron)
• heart: dilated cardiomyopathy
• pituitary: hypogonadotropic hypogonadism (impotence, decreased libido, amenorrhea)
• joints: arthralgia (any joint, but especially MCP joints), chondrocalcinosis

**Investigations**
• screening for individuals with clinical features and/or family history (1/4 chance of sibling having the disease)
  ▪ transferrin saturation (free Fe²⁺/TIBC) >45%
  ▪ serum ferritin >400 ng/mL
  ▪ HFE gene analysis: 90% of primary hemochromatosis involves C282Y allele, while H63D and S65C alleles also commonly involved and screened
• liver biopsy (generally used to detect cirrhosis or if potential for other causes of liver disease)
  ▪ markers of advanced fibrosis: if any of the following are present at the time of diagnosis → age >40, elevated liver enzymes, or ferritin >1000
  ▪ considered if compound heterozygote and potential other cause of liver injury (e.g. fatty liver, etc.)
  ▪ if C282Y/C282Y and no markers of advanced fibrosis, then biopsy generally not needed
• HCC screening if cirrhosis

**Treatment**
• phlebotomy: weekly or q2wk then lifelong maintenance phlebotomies q2-6mo
• deferoxamine if phlebotomy contraindicated (e.g. cardiomyopathy, anemia)
• primary hemochromatosis responds well to phlebotomy
• secondary hemochromatosis usually requires chelation therapy (administration of agents that bind and sequester iron, and then excreted)
Alcoholic Liver Disease

Definition
- fatty liver (all alcoholics): always reversible if alcohol stopped
- alcoholic hepatitis (35% of alcoholics): usually reversible if alcohol stopped
- cirrhosis (10-15% of alcoholics): potentially irreversible

Pathology
- several mechanisms, poorly understood
- ethanol oxidation to acetaldehyde
  - reduces NAD+ to NADH; increased NADH decreases ATP supply to liver, impairing lipolysis so fatty acids and triglycerides accumulate in liver
  - binds to hepatocytes evoking an immune reaction
- ethanol increases gut permeability leading to increased bacterial translocation
- alcohol metabolism causes
  - relative hypoxia in liver zone III > zone I
  - necrosis and hepatic vein sclerosis
- histology of alcoholic hepatitis
  - ballooned (swollen) hepatocytes often containing Mallory bodies, characteristically surrounded by neutrophils
  - large fat globules
  - fibrosis: space of Disse and perivenular

Clinical Manifestation
- >2-3 standard drinks/d in females and >3-6 standard drinks/d in men for >10 yr leads to cirrhosis, but only in about 10 to 20% of those who consume this amount daily on a continuous basis; cirrhosis risk increases with amount of alcohol consumed above threshold
- clinical findings do not accurately predict type of liver involvement
  - fatty liver
    - mildly tender hepatomegaly; jaundice rare
    - mildly increased transaminases <5x normal
  - alcoholic hepatitis
    - variable severity: mild to fatal liver failure
    - mild: stops drinking because feels unwell, resumes when feeling better (if assessed, findings of hepatitis, potentially mild jaundice and mildly elevated INR)
    - severe: stops drinking but feels unwell, low grade fever, RUQ discomfort, increased white blood cell count – mimics RLL pneumonia and cholecystitis

Investigations
- blood tests are non-specific, but in general:
  - AST:ALT >2:1 (usually <300)
  - increased GGT
  - CBC: increased MCV (mean corpuscular volume), increased WBC

Treatment
- alcohol cessation (see Psychiatry, PS19)
  - Alcoholics Anonymous, disulfiram, naltrexone, acamprosate
- multivitamin supplements (especially thiamine)
- caution with drugs metabolized by the liver
  - prednisone 40 mg OD x 28 d (taper over 2-4 wk) in subgroup with elevated bilirubin and INR, or if encephalopathy; but contraindicated in GI bleeding, renal failure, infection, pancreatitis
  - response (and subsequent decision to continue treatment) predicted by day 7 bilirubin (Lille score)
- pentoxyphilline decreases TNF, shown in one trial to reduce death, albeit only from renal failure; favorable side-effect profile

Prognosis
- prognosis: Maddrey’s discriminant function (based on PT and bilirubin) predicts mortality
  - fatty liver: complete resolution with cessation of alcohol intake
  - alcoholic hepatitis mortality
    - immediate: 30%-60% in the first 6 mo if severe
    - with continued alcohol: 70% in 5 yr
    - with cessation: 30% in 5 yr
  - alcoholic hepatitis DM
Non-Alcoholic Fatty Liver Disease

Definition
• spectrum of disorders characterized by macrovesicular hepatic steatosis
• most common cause of liver disease in North America

Pathology
• pathogenesis not well elucidated; insulin resistance implicated as key mechanism, leading to hepatic steatosis
• changes indistinguishable from those of alcoholic hepatitis despite negligible history of alcohol consumption

Risk Factors
• likely a component of the metabolic syndrome along with type 2 DM, HTN, hypertriglyceridemia
• rapid weight loss or weight gain

Clinical Manifestations
• often asymptomatic
• may present with fatigue, malaise, and vague RUQ discomfort
• elevated serum triglyceride/cholesterol levels and insulin resistance

Investigations
• elevated serum AST, ALT ± ALP; AST/ALT <1
• presents as echogenic liver texture on ultrasound
• liver biopsy diagnostic, but often necessary only for prognosis

Treatment
• no proven effective therapy other than gradual weight loss
• some evidence for vitamin E (800 U daily) in select groups
• pioglitazone can be considered if DM concomitantly present, but results in weight gain
• modification of risk factors is generally recommended, especially gradual weight reduction
• optimization of therapy for DM, hyperlipidemia, HTN

Prognosis
• most die from cardiovascular or cerebrovascular disease
• better prognosis than alcoholic hepatitis
  • <25% progress to cirrhosis over a 7-10 yr period
• risk of progression increases if inflammation or scarring occurs alongside fat infiltration (non-alcoholic steatohepatitis)
• other clinical indicators of unfavorable prognosis: DM, age, metabolic syndrome

Acute Liver Failure (formerly Fulminant Hepatic Failure)

Definition
• severe decline in liver function characterized by coagulation abnormality (INR>1.5) and encephalopathy
• in setting of previously normal liver
• rapid (<26 wk duration)

Pathology
• drugs (especially acetaminophen), hepatitis B (measure IgM anti-HBc because sometimes HBV-DNA and even HBsAg rapidly becomes negative), hepatitis A, hepatitis C (rare), ischemic, idiopathic

Treatment
• correct hypoglycemia, monitor level of consciousness, prevent GI bleeding with PPI, monitor for infection and multiorgan failure (usually requires ICU)
• consider liver biopsy before INR becomes too high
• chief value is to exclude chronic disease, less helpful for prognosis
• liver transplant (King’s College criteria can be used as prognostic indicator): consider early, especially if time from jaundice to encephalopathy >7 d (e.g. not extremely rapid), age <10 or >40, cause is drug or unknown, bilirubin >17.5 mg/dL, INR >3.5, creatinine >2.6 mg/dL
Cirrhosis

Definition
- liver damage characterized by diffuse distortion of the basic architecture and replacement with scar tissue and formation of regenerative nodules
- Stage 1 cirrhosis is compensated and asymptomatic, can last for 10-20 yr with almost normal life expectancy
- Stage 2 cirrhosis is the onset of first decompensation, typically development of ascites (most common), variceal bleeding, encephalopathy

Pathology
- fatty liver (alcohol, non-alcoholic fatty liver disease)
- chronic viral hepatitis (B, B+D, C; not A or E)
- autoimmune hepatitis
- hemochromatosis
- primary biliary cirrhosis
- chronic hepatic congestion
  - cardiac cirrhosis (chronic right heart failure, constrictive pericarditis)
  - hepatic vein thrombosis (Budd-Chiari)
- cryptogenic (i.e. no identifiable cause, although many of these patients may represent 'burnt-out NASH')
- rare: Wilson's disease, Gaucher's disease, α1-antitrypsin deficiency

Investigations
- definitive diagnosis is histologic (liver biopsy)
- other tests may be suggestive:
  - blood work: fall in platelet count <150 is the earliest finding, followed many yr later with rise in INR, fall in albumin, rise in bilirubin, fall in glucose level (pre-terminal event; see Figure 13)
  - FibroTest: combination of various clinical and biochemical markers that can predict degree of fibrosis
  - imaging:
    - U/S is the primary imaging modality but only finds advanced cirrhosis
    - CT to look for varices, nodular liver texture, splenomegaly, ascites
    - FibroScan: non-invasive tool using elastography (variable availability)
    - gastroscopy: varices or portal gastropathy

Treatment
- treat underlying disorder
- decrease insults (e.g. alcohol cessation, hepatotoxic drugs, immunize for Hep A and B if non-immune)
- follow patient for complications (esophageal varices, ascites, HCC defines stage 2 cirrhosis)
- prognosis: Child-Pugh Score and MELD score
- liver transplantation for end-stage disease if no alcohol for >6 mo; use MELD score

Table 18. Child-Pugh Score and Interpretation

Score: 5-6 (Child’s A), 7-9 (Child’s B), 10-15 (Child’s C)

*Note: Child’s classification is rarely used for shunting, but is still useful to quantitate the severity of cirrhosis
Complications

- hematologic changes in cirrhosis
  - pancytopenia from hypersplenism: platelets first, then WBC, then hemoglobin
  - decreased clotting factors resulting in elevated INR
  - relationship of INR to bleeding tendency is controversial; some patients may be hypocoagulable, others may be hypercoagulable
- variceal bleeds
  - half of patients with cirrhosis have gastroesophageal varices and one-third of these develop hemorrhage with an overall mortality of >30%
  - hepatic venous pressure gradient (HVPG) ≥10 mmHg is the strongest predictor of variceal development
  - management: resuscitation, antibiotic prophylaxis, vasoactive drugs (e.g. octreotide IV) combined with endoscopic band ligation or sclerotherapy, TIPS
- renal failure in cirrhosis
  - classifications
    - pre-renal (usually due to over-diuresis)
    - acute tubular necrosis (ATN)
    - hepatorenal syndrome (HRS)
      - Type I: sudden and acute renal failure (rapid doubling of creatinine over 2 wk)
      - Type II: gradual increase in creatinine with worsening liver function (creatinine doubling over years)
  - HRS can occur at any time in severe liver disease, especially after:
    - overdiuresis or dehydration, such as diarrhea, vomiting, etc.
    - GI bleed
    - sepsis
  - treatment for hepatorenal syndrome (generally unsuccessful at improving long-term survival)
    - for type I HRS: octreotide + midodrine + albumin (increases renal blood flow by increasing systemic vascular resistance)
    - definitive treatment is liver transplant
- hepatopulmonary syndrome
  - majority of cases due to cirrhosis, though can be due to other chronic liver diseases, such as non-cirrhotic portal HTN
  - thought to arise from ventilation-perfusion mismatch, intrapulmonary shunting and limitation of oxygen diffusion, failure of damaged liver to clear circulating pulmonary vasodilators vs. production of a vasodilating substance by the liver
  - clinical features
    - hyperdynamic circulation with cardiac output >7 L/min at rest and decreased pulmonary + systemic resistance (intrapulmonary shunting)
    - dyspnea, platypnea (increase in dyspnea in upright position, improved by recumbency) and orthodeoxia (desaturation in the upright position, improved by recumbency),
    - diagnosis via contrast-enhanced echocardiography: inject air bubbles into peripheral vein; air bubbles appear in left ventricle after third heartbeat (normal = no air bubbles; in ventricular septal defect, air bubbles seen <3 heart beats)
    - only proven treatment is liver transplantation

Hepatocellular Carcinoma

- see General Surgery, GS43

Liver Transplantation

- see General Surgery, GS44
Portal Hypertension

**Definition**
- pressure gradient between hepatic vein pressure and wedged hepatic vein pressure (corrected sinusoidal pressure) >5 mmHg

**Pathophysiology**
- 3 sites of increased resistance (remember pressure = flow x resistance)
  - pre-sinusoidal (e.g. portal vein thrombosis, schistosomiasis, sarcoidosis)
  - sinusoidal (e.g. cirrhosis, alcoholic hepatitis)
  - post-sinusoidal (e.g. right-sided heart failure, hepatic vein thrombosis, veno-occlusive disease, constrictive pericarditis)

**Complications**
- GI bleeding from varices in esophagus, less commonly in stomach, even less frequently from portal hypertensive gastropathy
- ascites
- hepatic encephalopathy
- thrombocytopenia
- renal dysfunction
- sepsis
- arterial hypoxemia

**Management**
- non-selective β-blockers (propanolol, nadolol) decrease risk of bleeding from varices
- TIPS: to decrease portal venous pressure
  - shunt between portal and hepatic vein via transjugular vein catheterization and percutaneous puncture of portal vein
  - can be used to stop acute bleeding or prevent rebleeding or treat ascites
  - shunt usually remains open for <1 yr
- complications: hepatic encephalopathy, deterioration of hepatic function
- contraindicated with severe liver dysfunction
- most commonly used as a "bridge" to liver transplant
- other surgically created shunts (rare): portacaval, distal spleno-renal (Warren shunt)

Hepatic Encephalopathy

**Definition**
- spectrum of potentially reversible neuropsychiatric syndromes secondary to liver disease diagnosed after ruling out other causes for symptoms (e.g. structural/metabolic)

**Pathophysiology**
- portosystemic shunt around hepatocytes and decreased hepatocellular function increase level of systemic toxins (believed to be ammonia from gut, mercaptans, fatty acids, amino acids) which go to the brain

**Precipitating Factors**
- nitrogen load (GI bleed, protein load from food intake, renal failure, constipation)
- drugs (narcotics, CNS depressants)
- electrolyte disturbance (hypokalemia, alkalosis, hypoxia, hypovolemia)
- infection (spontaneous bacterial peritonitis)
- deterioration in hepatic function or superimposed liver disease

**Stages**
- I: apathy, restlessness, reversal of sleep-wake cycle, slowed intellect, impaired computational abilities, impaired handwriting
- II: asterixis, lethargy, drowsiness, disorientation
- III: stupor (rousable), hyperactive reflexes, extensor plantar responses
- IV: coma (response to painful stimuli only)

**Investigations**
- clinical diagnosis: supported by laboratory findings and exclusion of other neuropsychiatric diseases
- rule out
  - non-liver-related neuropsychiatric disease in a patient with liver problems (e.g. alcohol withdrawal or intoxication, sedatives, subdural hematoma, metabolic encephalopathy)
  - causes of metabolic encephalopathy (e.g. renal failure, respiratory failure, severe hypoponatremia, hypoglycemia)
  - characteristic EEG findings: diffuse (non-focal), slow, high amplitude waves
Treatment
- treat underlying precipitating factors
- decrease generation of nitrogenous compounds
  - decrease dietary protein to 50 g/d; vegetable protein is better tolerated than animal protein
  - lactulose: titrated to achieve 2 to 3 soft stools per day
    - prevents diffusion of NH₃ (ammonia) from the colon into blood by lowering pH and forming non-diffusible NH₄ (ammonium)
    - serves as a substrate for incorporation of ammonia by bacteria, promotes growth in bowel lumen of bacteria which produce minimal ammonia
    - also acts as a laxative to eliminate nitrogen-producing bacteria from colon
  - if inadequate response with lactulose may try antibiotics
    - broad-spectrum antibiotics (metronidazole, rifaximin) eliminate ammonia producing bacteria from bowel lumen
  - non-absorbable antibiotic rifaximin probably most effective treatment
- best acute treatment in comatose patient is lactulose enemas

Ascites

Definition
- accumulation of excess fluid in the peritoneal cavity

Etiology

Table 19. Serum-Ascites Albumin Gradient as an Indicator of the Causes of Ascites

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>

</tbody>
</table>

* In nephrotic syndrome: decreased serum [Alb] to begin with therefore gradient not helpful

Pathogenesis
- key factor in pathogenesis is increased sodium (and water) retention by the kidney for reasons not fully understood. Theories include:
  - underfill hypothesis: first step in ascites formation is increased portal pressure and low oncotic pressure (e.g. low serum albumin) driving water out of the splanchnic portal circulation into abdominal cavity; the resulting decreased circulating volume causes secondary sodium retention by the kidney
  - overfill hypothesis: cirrhosis directly causes increased sodium retention by the kidney in the absence of hypovolemia and ascites arises secondarily
  - peripheral arterial vasodilation theory (most popular): as portal HTN develops in cirrhosis, production of local mediators such as nitric oxide lead to splanchnic arterial vasodilation which ultimately results in reduction of effective arterial volume and compensatory sodium and fluid retention by the kidneys (i.e. circulation volume is increased, as per overflow hypothesis, but relatively underfilled, as per underfill hypothesis)

Diagnosis
- abdominal ultrasound
- physical exam (clinically detectable when >500 mL)
  - bulging flanks, shifting dullness, fluid-wave test positive
  - most sensitive symptom: ankle swelling

Investigations
- diagnostic paracentesis
  - 1st aliquot: cells and differential
  - 2nd aliquot: chemistry (especially albumin, but also total protein; amylase if pancreatitis; TG and chylomicrons if turbid and suspect chylous ascites)
  - 3rd aliquot: C&S, Gram stain
  - 4th aliquot: cytology (usually positive in peritoneal carcinomatosis)

Primary Prophylaxis of Spontaneous Bacterial Peritonitis Delays Hepatorenal Syndrome and Improves Survival in Cirrhosis

Gastroenterology 2007;133:818-824

Study: RCT, double-blinded study with 1 yr follow-up.

Population: 68 patients with cirrhosis, ascites, ascitic fluid protein <1.5 g/dL, and impaired renal function or severe liver failure.

Intervention: General, regional, or combined anesthesia to patients undergoing a surgical procedure.

Main Outcome: Norfloxacin vs. placebo.

Results: There was a significant reduction of patients developing spontaneous bacterial peritonitis (SBP) (6% vs. 30%, p=0.02) and spontaneous bacteremia (6% vs. 12%, p=0.05) with norfloxacin therapy. There were significantly fewer patients who developed all-cause renal failure (7 vs. 16, p=0.03) and hepaticorenal syndrome (HRS) with norfloxacin therapy. Probability of survival at 3 mo (94% vs. 62%, p=0.02) and 1 yr (60% vs. 40%, p=0.003) were high in patients treated with norfloxacin.

Conclusion: Primary prophylaxis with norfloxacin in patients with advanced cirrhosis reduced SBP, HRS, and improved 1 yr survival.
therapeutic/palliative paracentesis indicated
- IV albumin (not indicated if <5 L removed by paracentesis)
- TIPS in an appropriate patient (no contraindications) with potential transplant-free survival advantage
- liver transplantation should be considered in every case, since development of ascites in patients with cirrhosis are associated with 50% 2 yr mortality

Complication: Primary/Spontaneous Bacterial Peritonitis
- primary/spontaneous bacterial peritonitis (SBP)
  - complicates ascites, but does not cause it (occurs in 10% of cirrhotic ascites); higher risk in patients with GI bleed
  - 1/3 of patients are asymptomatic, thus do not hesitate to do a diagnostic paracentesis in ascites even if no clinical indication of infection
  - fever, chills, abdominal pain, ileus, hypotension, worsening encephalopathy, acute kidney injury
  - Gram-negatives compose 70% of pathogens: E. coli (most common), Streptococcus, Klebsiella

  - diagnosis
    - absolute neutrophil count in peritoneal fluid >0.25x10^6 cells/L (250 cells/mm³)
    - Gram stain positive in only 10-50% of patients
    - culture positive in <80% of patients (not needed for diagnosis)
  - prophylaxis: consider in patients with:
    - cirrhosis or GI bleed: ceftriaxone IV daily or norfloxacin bid x 7 d
    - previous episode of SBP: long-term prophylaxis with daily norfloxacin or TMP-SMX
  - treatment
    - IV antibiotics (cefotaxime 2 g IV q8h or ceftriaxone 2g IV daily is the treatment of choice for 5 d; modify if response inadequate or culture shows resistant organisms)
    - IV albumin (1.5 g/kg at time of diagnosis and 1 g/kg on day 3) decreases mortality by lowering risk of acute renal failure

Biliary Tract

Jaundice
- see Table 2, G6 and Figures 15 and 16, G42

Signs and Symptoms
- dark urine, pale stools: suggests that bilirubin elevation is from direct fraction
- pruritus: suggests chronic disease, cholestasis
- abdominal pain: suggests biliary tract obstruction from stone or pancreatic tumor (obstructive jaundice)
- painless jaundice in the elderly: think of pancreatic cancer
- kernicterus: rarely seen in adults due to maturation of blood brain barrier

Investigations
- blood work: CBC, bilirubin (direct and total), liver enzymes (AST, ALT, ALP, GGT), liver function tests (INR/PT, PTT, albumin), amylase
- U/S or CT for evidence of bile duct obstruction (e.g. bile duct dilation)
- direct bile duct visualization
  - magnetic resonance cholangiopancreatography (MRCP): non-invasive
  - endoscopic ultrasound (EUS): sensitive for stones and pancreatic tumors
  - endoscopic retrograde cholangiopancreatography (ERCP): invasive, most accurate, allows for therapeutic intervention
  - percutaneous transhepatic cholangiography (PTC): if ERCP fails, if obstruction is in liver
**Gilbert’s Syndrome**

**Definition**
- Mild decrease in glucuronyltransferase activity leading to defective conjugation of bilirubin.

**Etiology/Epidemiology**
- Some patients have decreased hepatobiliary uptake.
- Affects 7% of the population, especially males.
- Autosomal dominant, 70% due to a mutation in the UGT gene.

**Signs and Symptoms**
- Presents in teens-20s, often an incidental finding.
- Only manifestation is intermittent jaundice with increased serum unconjugated bilirubin developing most characteristically while fasting, or at times of acute illness; no other clinical implications.

**Treatment**
- None indicated (entirely benign).

---

**Sclerosing Cholangitis**

**Definition**
- Inflammation of biliary tree (intra and/or extrahepatic bile ducts) leading to scarring and lumen obliteration.

**Etiology**
- Primary/idiopathic (most common)
  - Associated with IBD, more commonly UC, in up to 70% of patients (usually male).
  - One of the most common indications for transplant.
- Secondary (less common)
  - Long-term choledocholithiasis.
  - Cholangiocarcinoma.
  - Surgical/traumatic injury (iatrogenic).
  - Contiguous inflammatory process.
  - Post-ERCP.
  - Associated with HIV/AIDS (“HIV cholangiopathy”).
  - IgG4-related disease.

**Signs and Symptoms**
- Often insidious, may present with fatigue and pruritus.
- May present with signs of episodic bacterial cholangitis secondary to biliary obstruction.

**Diagnosis**
- Increased ALP (hallmark), less often increased bilirubin.
- Mildly increased AST, usually <300 U/L.
- p-ANCA (30-80%), elevated IgM (40-50%).
ERCP shows narrowing and dilatations of bile ducts that may result in “beading”, both intrahepatic and extrahepatic bile ducts
  - if intrahepatic narrowing only, do anti-mitochondrial antibody to rule out PBC

Complications
- repeated bouts of cholangitis may lead to complete biliary obstruction with resultant secondary biliary cirrhosis and hepatic failure
- increased incidence of cholangiocarcinoma (10-15%): difficult to diagnose and treat

Management
- image bile duct (MRCP) at least annually for early detection of cholangiocarcinoma (controversial)
- endoscopic sphincterotomy, biliary stent in selected cases of dominant CBD stricture
- antibiotics for cholangitis
- suppurative cholangitis requires emergency drainage of pus in CBD
- liver transplantation appears the best treatment for advanced sclerosing cholangitis (nearly 90% 1 yr survival; mean follow-up from time of diagnosis to need for transplant is 10 yr)
- ursodiol: previously recommended, but studies suggest that at least in high doses it increases mortality

Prognosis
- unfavorable regardless of treatment
- mean survival after diagnosis remains 4-10 yr

Primary Biliary Cirrhosis

Definition
- chronic inflammation and fibrous obliteration of intrahepatic bile ductules

Etiology/Epidemiology
- likely autoimmune (associated with Sjögren’s syndrome, scleroderma, CREST syndrome, RA, thyroiditis)
- affects mainly middle-aged women (M:F = 1:9)

Signs and Symptoms
- often asymptomatic
- initial symptoms: pruritus, fatigue
- chronic: jaundice and melanosis (darkening skin) and other signs of cholestasis
- end-stage: hepatocellular failure, portal HTN, ascites
- high incidence of osteoporosis

Investigations
- increased ALP, GGT; bilirubin rises in later stage
- positive anti-mitochondrial antibodies (AMA; 95% specificity and sensitivity)
- increased serum cholesterol (mild increase in LDL, larger increase in HDL)
  - may have: xanthelasmas, xanthomas
- liver biopsy confirms diagnosis and stages severity
- normal bile duct on MRCP rules out bile duct obstruction which can mimic PBC
- recently described “overlap” syndromes with autoimmune cholangitis, autoimmune hepatitis, sclerosing cholangitis

Clinical Course
- can be fatal, although not all asymptomatic patients show progression

Treatment
- treat with ursodiol (less frequently colchicine, methotrexate)
- cholestyramine (for pruritus and hypercholesterolemia)
- calcium and vitamin D for low bone density; bisphosphonates if osteoporosis severe
- monitor for thyroid disease
- liver transplant if disease severe, progressive

Secondary Biliary Cirrhosis

Definition
• cirrhosis from prolonged partial or total obstruction of major bile ducts

Etiology
• acquired: post-operative strictures, chronic pancreatitis, sclerosing cholangitis, stone in bile duct
• congenital: CF, congenital biliary atresia, choledochal cysts

Diagnosis
• cholangiography and liver biopsy

Treatment
• treat obstruction, give antibiotics for cholangitis prophylaxis

Biliary Colic, Cholecystitis

• see General Surgery, GS46

Ascending Cholangitis

• see General Surgery, GS48

Definition
• infection of the biliary tree

Etiology
• stasis in the biliary tract due to obstruction or stricture (usually from previous cholecystectomy)
• infection originates in the duodenum or spreads hematogenously from the portal vein
• bacteria
  ▪ *E. coli*, *Klebsiella*, *Enterobacter*, *Enterococcus*
  ▪ co-infection with *Bacteroides* and *Clostridia* can occur

Signs and Symptoms
• Charcot’s triad: fever, RUQ pain, jaundice (50-70%)
• Reynold’s Pentad in patients with suppurative cholangitis: fever, RUQ pain, jaundice, hypotension, altered mental status

Diagnosis
• increased WBC
• usually increased ALP and bilirubin, ALT variably elevated
• blood culture
• abdominal U/S: CBD dilation, stones

Treatment
• most important is drainage, ideally via ERCP, but if necessary by percutaneous biliary or surgical routes
• antibiotic therapy; broad spectrum to cover Gram-negatives, *Enterococcus*, and anaerobes (especially if CBD manipulation); no clear consensus on antibiotic choice but consider:
  ▪ ampicillin + sulbactam or piperacillin/tazobactam
  ▪ metronidazole + 3rd generation cephalosporin (e.g. ceftriaxone) or fluoroquinolone (e.g. ciprofloxacin or levofloxacin)
  ▪ carbapenem monotherapy (e.g. imipenem or meropenem)

Prognosis
• good with effective drainage and antibiotics in mild to moderate cases
• high mortality (~50%) in patients with Reynold’s Pentad
Pancreas

Pancreatic Enzyme Abnormalities

Causes of Increased Serum Amylase

- pancreatic disease
  - pancreatitis, pancreatic duct obstruction (e.g. ampullary cancer), pseudocyst, abscess, ascites, trauma, cancer
- non-pancreatic abdominal disease
  - biliary tract disease, bowel obstruction/ischemia, perforated or penetrating ulcer, ruptured ectopic pregnancy, aneurysm, chronic liver disease, peritonitis
- non-abdominal disease
  - cancer (lung, ovary, esophagus, etc.), salivary gland lesions, bulimia, renal transplant/insufficiency, burns, ketoacidosis
  - macroamylasemia

Causes of Increased Serum Lipase

- pancreatic disease: same as above
- non-pancreatic abdominal disease (mild elevations only): same as above
- non-abdominal disease
  - macrolipasemia
  - renal failure

Acute Pancreatitis

Etiology

- Idiopathic: thought to be hypertensive sphincter or microlithiasis
- Gallstones (45%)
- Alcohol (35%)
- Tumors: pancreas, ampulla, choledochocoele
- Scorpion stings
- Microbiological
  - bacterial: Mycoplasma, Campylobacter, TB, M. avium intracellulare, Legionella, leptospirosis
  - viral: mumps, rubella, varicella, viral hepatitis, CMV, EBV, HIV, Coxsackie virus, echovirus, adenovirus
  - parasites: ascariasis, clonorchiasis, echinococcosis
- Autoimmune: SLE, polyarteritis nodosa (PAN), Crohn's disease
- Surgery/trauma
  - manipulation of sphincter of Oddi (e.g. ERCP), post-cardiac surgery, blunt trauma to abdomen, penetrating peptic ulcer
- Hyperlipidemia (TG >11.3 mmol/L; >1000 mg/dL), Hypercalcemia, Hypothermia
- Emboli or ischemia
- Drugs/toxins
  - azathioprine, mercaptopurine, furosemide, estrogens, methylprednisolone, H2-blockers, valproic acid, antibiotics, acetaminophen, salicylates, methanol, organophosphates, steroids (controversial)

Pathogenesis

- activation of proteolytic enzymes within pancreatic cells, starting with trypsin, leading to local and systemic inflammatory response
- in gallstone pancreatitis, this is due to mechanical obstruction of the pancreatic duct by stones
- in ethanol-related pancreatitis, pathogenesis is unknown
- in rare genetic diseases, mutations prevent the physiological breakdown of trypsin required normally to stop proteolysis (e.g. mutant trypsin in hereditary pancreatitis, mutation in SPINK 1 gene which normally inhibits activated trypsin); may be model for ethanol-related pancreatitis

Pathology

- mild (interstitial)
  - peri-pancreatic fat necrosis
  - interstitial edema
- severe (necrotic)
  - extensive peri-pancreatic and intra-pancreatic fat necrosis
  - parenchymal necrosis and hemorrhage \rightarrow infection in 60%
  - release of toxic factors into systemic circulation and peritoneal space (causes multi-organ failure)
- severity of clinical features may not always correlate with pathology
• 3 phases
  ▪ local inflammation + necrosis → hypovolemia
  ▪ systemic inflammation in multiple organs, especially in lungs, usually after IV fluids given → pulmonary edema
  ▪ local complications 2 wk after presentation → pancreatic sepsis/abscess

Signs and Symptoms
• pain: epigastric, noncolicky, constant
  ▪ may radiate to back
  ▪ may improve when leaning forward (Inglefingen’s sign)
• tenderness:
  ▪ tender rigid abdomen; guarding
  ▪ N/V
  ▪ abdominal distention from paralytic ileus
• fever: chemical, not due to infection
  ▪ jaundice: compression or obstruction of bile duct
  ▪ Cullen’s/Gray-Turner’s signs
  ▪ tetany: transient hypocalcemia
  ▪ hypovolemic shock: can lead to renal failure
  ▪ acute respiratory distress syndrome
  ▪ coma

Investigations
• increased serum pancreatic enzymes: amylase, lipase (more specific)
• ALT >150 specific for biliary cause
• increased WBC, glucose, low calcium
• imaging:
  ▪ CT most useful for diagnosis and prognosis
    ▪ x-ray: ‘sentinel loop’ (dilated proximal jejunum), calcification, and “colon cut-off sign” (colonic spasm)
  ▪ U/S: useful for evaluating biliary tree (67% sensitivity, 100% specificity)
  ▪ CT scan with IV contrast: useful for diagnosis and prognosis because contrast seen only in viable pancreatic tissue, non-viable areas can be biopsied percutaneously to differentiate sterile from infected necrosis
  ▪ ERCP or MRCP if cause uncertain, assess for duct stone, pancreatic or ampullary tumor,
  ▪ perianal edema
  ▪ aspiration biopsy (see sidebar)

Prognosis
• usually a benign, self-limiting course, single or recurrent
• occasionally severe leading to:
  ▪ shock
  ▪ pulmonary edema
  ▪ multi-organ dysfunction syndrome
  ▪ GI ulceration due to stress
  ▪ death
• mortality according to Ranson’s criteria (see sidebar)
  ▪ ≤2 criteria = <5% mortality
  ▪ 3–4 criteria = 15–20%
  ▪ 5–6 criteria = 40%
  ▪ ≥7 criteria = >99%
• multiple other prognostic indices available, more accurate than Ranson but difficult to remember (e.g. APACHE)

Treatment
• goals (only supportive therapy available)
  (1) hemodynamic stability
  (2) analgesia
  (3) oxygen
  (4) stop progression of damage (difficult)
  (5) treat local and systemic complications
• antibiotics controversial except in documented infection (use cephalosporins, imipenem)
• aspirate necrotic areas of pancreas to diagnose infection; drain if infected
• IV fluids (crystalloid or colloid)
• NG suction (reduces pressure)
• nutritional support:
  ▪ nasojejunal feeding tube or TPN if cannot tolerate enteric feeds
  ▪ recent evidence supports nasogastric enteral (or oral if feasible) feeds
  ▪ no benefit: glucagon, atropine, aprotinin, H2-blockers, peritoneal lavage
• follow clinically and CT/ultrasound to exclude complications
• chief role of surgery is to drain fluid or excise necrotic tissue (necrosectomy) in the case of infected necrotic tissue (try to delay for >2 wk to allow demarcation between viable and necrotic tissue)

Ranson’s Criteria: Prognostic Indicator of Mortality in Pancreatitis not due to Gallstones

At Admission
G: Blood Glucose > 11 mmol/L (> 200 mg/dL) (with no history of hyperglycemia)
A: Age > 55
L: Serum LDH > 350 IU/L
H: ALP > 350 IU/L
W: WBC > 16 x 109/L (16,000/mm3)

During First 48 h
C: Serum Calcium < 2 mmol/L (< 8 mg/dL)
T: Hematocrit drop > 10%
O: Arterial P O2 < 60 mmHg
N: Base deficit > 6 mmol/L (> 4 mEq/L)
E: BUN rise > 1.8 mmol/L (> 5 mg/dL)
S: Estimated fluid Sequestration > 6 L

• Difficult course if 2 criteria present
• High mortality if ≥ 3 criteria present

Note:
• coma
• acute respiratory distress syndrome
• hypovolemic shock: can lead to renal failure
• tetany: transient hypocalcemia
• coma
• multi-organ dysfunction syndrome
• hypovolemic shock: can lead to renal failure
• fever: chemical, not due to infection

Increased Amylase
• Sensitive, not specific

Increased Lipase
• Higher sensitivity and specificity
• Stays elevated longer

References:
Am J Gastroenterol 2008;103:104-110
Gastroenterology Pancreas Essential Med Notes 2015
Late Complications
- pseudocysts: follow if asymptomatic, drain if symptomatic or growing
  - drain: choice of endoscopic, percutaneous under radiological guidance, or surgical
- infected necrosis/abscesses: antibiotics + percutaneous drainage, endoscopic vs. surgical
- bleeding: (1) gastric varices if splenic vein thrombosis, (2) pseudoaneurysm of vessels in areas of necrosis, especially splenic artery, (3) duodenal ulcer related to compression of duodenum by enlarged pancreas
- splenic and portal vein thrombosis: no effective therapy described, anticoagulation not proven, hazardous
- rare: DM, pancreatic duct damage

Chronic Pancreatitis

Definition
- irreversible damage to pancreas characterized by:
  1. pancreatic cell loss (from necrosis)
  2. inflammation
  3. fibrosis

Etiology/Pathophysiology
- alcohol (most common)
  - causes a larger proportion (>90%) of chronic pancreatitis than acute pancreatitis
  - changes composition of pancreatic juice (e.g. increases viscosity)
  - decreases pancreatic secretion of pancreatic stone protein (lithostathine) which normally solubilizes calcium salts
    - precipitation of calcium within pancreatic duct results in duct and gland destruction
  - toxic effect on acinar and duct cells – directly or via increasing free radicals
  - acinar cell injury leads to cytokine release, which stimulates pancreatic stellate cells to form collagen (leading to fibrosis)
  - varying degrees of ductular dilatation, strictures, protein plugs, calcification
  - no satisfactory theory to explain why only a minority of alcoholics develop pancreatitis
- unusual causes
  - CF
  - severe protein-calorie malnutrition
  - hereditary
  - idiopathic

Signs and Symptoms
- early stages
  - recurrent attacks of severe abdominal pain (upper abdomen and back)
  - chronic painless pancreatitis: 10%
- late stages: occurs in 15% of patients
  - malabsorption syndrome when >90% of function is lost, steatorrhea
  - DM, calcification, jaundice, weight loss, pseudocyst, ascites, GI bleed

Investigations
- laboratory
  - increase in serum glucose
  - increase in serum ALP, less commonly bilirubin (jaundice)
  - serum amylase and lipase usually normal
- AXR: pancreatic calcifications
- U/S or CT: calcification, dilated pancreatic ducts, pseudocyst
- MRCP or ERCP: abnormalities of pancreatic ducts-narrowing and dilatation
- EUS: abnormalities of pancreatic parenchyma and pancreatic ducts
- 72 h fecal fat test: measures exocrine function
- secretin test: gold standard, measures exocrine function but difficult to perform, unpleasant for patient, expensive
- fecal pancreatic enzyme measurement (elastase-1, chymotrypsin): available only in selected centers

Management
- most common problem is pain, difficult to control
- general management
  - total abstinence from alcohol
  - enzyme replacement may help pain by resting pancreas via negative feedback
  - analgesics
  - celiac ganglion blocks
  - time: pain decreases with time as pancreas “burns out”
- endoscopy: sphincterotomy, stent if duct dilated, remove stones from pancreatic duct

Gallstones only cause acute pancreatitis (not chronic pancreatitis)

Symptoms of Chronic Pancreatitis
- Abdominal pain
- Diabetes
- Steatorrhea

Etiology = Almost Always Alcohol

Treatment
- Alcohol abstinence
- Pancreatic enzyme replacement
- Analgesics
- Pancreatic resection if ductular blockage

Gallstones only cause acute pancreatitis (not chronic pancreatitis)
• surgery: drain pancreatic duct (pancreaticojejunostomy) if duct dilated (more effective than endoscopy); resect pancreas if duct contracted
• steatorrhea
  ▪ pancreatic enzyme replacement
  ▪ restrict fat, increase carbohydrate and protein (may also decrease pain)
  ▪ neither endoscopy nor surgery can improve pancreatic function

**Autoimmune Pancreatitis**

• most commonly presents as a mimicker of pancreatic cancer (pancreatic mass detected because of jaundice ± abdominal pain)

**Investigations**

• histology: lymphocyte and plasma cell infiltration of pancreas
• imaging: focal or diffuse enlargement of pancreas on CT or MRI, sausage shaped, low density rim around pancreas
• serology: increased serum IgG4
• other organs involvement: sialadenitis, retroperitoneal fibrosis, biliary duct narrowing, nephritis

**Treatment**

• responds to prednisone

**Clinical Nutrition**

**Determination of Nutritional Status**

• corrected weight loss (expressed as body mass index [kg/m²]) is most important parameter in assessing need for nutritional support

**Investigations**

• plasma proteins: albumin, pre-albumin (shorter half life than albumin), transferrin
  ▪ decrease may indicate decreased nutritional status or disease state
• thyroid-binding globulin, retinol-binding protein (may be too sensitive)
• anthropometry (e.g. triceps skinfold thickness), grip strength less often used

**Enteral Nutrition**

**Definition**

• enteral nutrition (tube feeding) is a way of providing food through a tube placed in the stomach or the small intestine
• choice of tubes: nasogastric (NG), nasojejunal (NJ), percutaneous endoscopic gastrostomy (G-tube), percutaneous endoscopic jejunostomy (J-tube) or tubes can be placed radiologically, surgically

**Indications**

• oral feeding inadequate or contraindicated

**Feeds**

• polymeric feeds contain whole protein, carbohydrate, fat as a liquid, with or without fiber
• elemental feeds contain protein as amino acids, carbohydrate as simple sugars, fat content low (therefore high osmolarity)
• specific diets: low carbohydrate/high fat solution for ventilated patients (carbohydrate has a high respiratory quotient so minimizes carbon dioxide production), high energy, low electrolyte solutions for dialysis patients

**Relative Contraindications**

• non-functioning gut (e.g. intestinal obstruction, enteroenteral or entero-cutaneous fistulae)
• uncontrolled diarrhea
• GI bleeding

Hypomagnesemia may be an initial sign of short bowel syndrome in patients who have undergone surgical bowel resection.

Most Common Indications for Artificial Nutrition Support:

• Preexisting nutritional deprivation
• Anticipated or actual inadequate energy intake by mouth
• Significant multiorgan system disease
Complications

- aspiration
- diarrhea
- refeeding syndrome (rare): carbohydrate can stimulate excessive insulin release, leading to cellular uptake and low serum levels of phosphate, magnesium, potassium
- overfeeding syndrome (rare): hypertonic dehydration, hyperglycemia, hypercapnea, azotemia (from excess protein)

Enteral Nutrition Advantages over Parenteral Nutrition

- far fewer serious complications (especially sepsis)
- nutritional requirements for enteral administration better understood
- can supply gut-specific fuels such as glutamine and short chain fatty acids
- nutrients in the intestinal lumen prevent atrophy of the gut and pancreas
- prevents gallstones by stimulating gallbladder motility
- much less expensive

Parenteral Nutrition

Definition

- parenteral nutrition is the practice of feeding a person intravenously, bypassing the usual process of eating and digestion

Indications

- short-term (<1 mo)
  - whenever GI tract not functioning
  - only situations where PN has been well shown to increase survival are after bone marrow transplant and in short bowel syndrome, some evidence for benefit in gastric cancer, but often used in ICU, perioperatively, and in difficult to control sepsis
  - pre-operative: only useful in severely malnourished (e.g. loss of >15% of pre-morbid weight, serum albumin <28 g/L or <2.8 g/dL), and only if given for ≥2 wk
  - renal failure: PN shown to increase rate of recovery; no increase in survival
  - liver disease: branched chain amino acids may shorten duration of encephalopathy; no increase in survival
  - IBD: PN closes fistulae and heals acute exacerbations of mucosal inflammation, but effect is transient (EN is equally effective)
  - some evidence for efficacy, but convincing data not available for:
    - radiation/chemotherapy-induced enteritis
    - AIDS with wasting diarrhea
    - severe acute pancreatitis
- long-term (>1 mo): can be given at home
  - severe untreatable small bowel disease (e.g. radiation enteritis, extensive CD, high output fistulae)
  - following surgical resection of >70% of bowel (e.g. bowel infarction)
  - severe motility diseases (e.g. scleroderma affecting bowel)

Relative Contraindications

- functional GI tract for enteral nutrition
- active infection; at least until appropriate antibiotic coverage
- inadequate venous access; triple-lumen central venous lines usually prevent this problem
- unreliable patient or clinical setting

Complications of PN

- sepsis: most serious of the common complications
- mechanical pneumothorax from insertion of central line, catheter migration and thrombosis, air embolus
- metabolic: CHF, hyperglycemia, gallstones, cholestasis

Whenever possible, enteral nutrition is ALWAYS preferable over parenteral nutrition

<td>Same as above</td>
<td>Same as above</td>
<td>Same as above</td>
<td>Same as above</td>
</tr>
<tr>
<td>Histamine H₂-Receptor</td>
<td>ranitidine</td>
<td>Zantac®</td>
<td>300 mg PO OD or 150 mg bid</td>
<td>Inhibits gastric histamine H₂-receptors</td>
<td>Duodenal ulcer, gastric ulcer, NSAID-associated gastric and duodenal ulcers, ulcer prophylaxis, reflux esophagitis, symptomatic GERD, Zollinger-Ellison syndrome</td>
<td>Hypersensitivity to drug</td>
<td>Confusion, dizziness, headache, arrhythmias, constipation, nausea, agranulocytosis, pancytopenia, depression</td>
</tr>
<tr>
<td>Antagonists</td>
<td>famotidine</td>
<td>Pepcid®</td>
<td>Oral therapy: duodenal/gastric ulcers: 40 mg qhs GERD: 20 mg bid IV therapy: 20 mg bid</td>
<td>Same as above</td>
<td>Same as above</td>
<td>Same as above</td>
<td>Same as above</td>
</tr>
<tr>
<td>Stool Softener</td>
<td>docusate sodium</td>
<td>Colace®</td>
<td>100-400 mg PO OD, divided in 1-4 doses</td>
<td>Promotes incorporation of water into stool</td>
<td>Relief of constipation</td>
<td>Presence of abdominal pain, fever, N/V</td>
<td>Throat irritation, abdominal cramps, rashes</td>
</tr>
<tr>
<td>Osmotic Laxatives</td>
<td>lactulose</td>
<td>Lactulose/Constulose®</td>
<td>Constipation: 15-30 mL PO OD bid</td>
<td>Poorly absorbed in GI tract and is broken down by colonic bacteria into lactic acid into colon, increases osmotic colonic contents, increases stool volume</td>
<td>Chronic constipation, prevention and treatment of portal-systemic encephalopathy</td>
<td>Patients who require a low galactose diet</td>
<td>Flatulence, intestinal cramps, nausea, diarrhea if excessive dosage</td>
</tr>
<tr>
<td></td>
<td>Peg3350</td>
<td>Lax-a-day®/Golytely®</td>
<td>Constipation: 17 g powder dissolved in 4-8 oz liquid PO OD</td>
<td>Osmotic agent causes water retention in stool and promotes frequency of stool</td>
<td>Relief of constipation</td>
<td>Colonoscopy prep</td>
<td>Hypersensitivity to drug</td>
</tr>
<tr>
<td>Prokinetic Laxatives</td>
<td>senna</td>
<td>Senokot®</td>
<td>Tablets: 1-4 PO qhs</td>
<td>Induce peristalsis in lower colon</td>
<td>Constipation</td>
<td>Patients with acute abdomen</td>
<td>Abdominal cramps, discoloration of breast milk, urine, feces, melanosist coli and atomic colon from prolonged use (controversial)</td>
</tr>
<tr>
<td></td>
<td>bisacodyl</td>
<td>Bisacodyl®</td>
<td>5-30 mg PO OD (start at 10 mg for bowel preparation)</td>
<td>Enteric nerve stimulation and local contact-induced secretory effects. Colonic movements</td>
<td>Constipation</td>
<td>Preparation of bowel for procedure</td>
<td>GI obstruction, Gastroenteritis</td>

Basic Anatomy Review

Lateral Abdominal Wall Layers and their Continuous Spermatic and Scrotal Structures (superficial to deep)
1. skin (epidermis, dermis, subcutaneous fat)
2. superficial fascia
   - Camper’s fascia (fatty) → Dartos fascia
   - Scarpa’s fascia (membranous) → Colles’ superficial perineal fascia
3. muscle (see Figure 2 and Figure 3)
   - external oblique → inguinal ligament → external spermatic fascia and fascia lata
   - internal oblique → cremasteric muscle/fascia
   - transversus abdominis → posterior inguinal wall
4. transversalis fascia → internal spermatic fascia
5. preperitoneal fat
6. peritoneum → tunica vaginalis

Midline Abdominal Wall Layers (superficial to deep)
1. skin
2. superficial fascia
3. rectus abdominis muscle; in rectus sheath, divided by linea alba
   - above arcuate line (midway between symphysis pubis and umbilicus)
     - anterior rectus sheath = external oblique aponeurosis and anterior leaf of internal oblique aponeurosis
     - posterior rectus sheath = posterior leaf of internal oblique aponeurosis and transversus abdominis aponeurosis
   - below arcuate line
     - aponeuroses of external oblique, internal, oblique, transversus abdominis all pass in front of rectus abdominis
4. arteries: superior epigastric (branch of internal thoracic), inferior epigastric (branch of external iliac)
5. transversalis fascia
6. superficial inguinal ring
   - deep inguinal ring
   - Membranous layer of superficial fascia (Scarpa’s fascia)

Figure 1. Abdominal incisions

- Access to RUG or LUQ contents i.e. gallbladder, spleen
- Access to stomach, duodenum, gallbladder, liver, transverse colon
- Can make similar incision in each quadrant for access to each quadrant’s contents
- Not commonly used
- Post-operative ventral hernias common
- Incision made at outer 1/3 - medial 2/3 border of rectus
- Modification of paramedian but with lower risk of dehiscence or ventral hernia
- Not commonly used
- Access to pelvic organs, sigmoid cecum, and rectum
- Suprapubic incision for access to pelvic cavity
- Access to appendix

Figure 2. Continuity of the abdominal wall with layers of the scrotum and spermatic cord
### General Surgery Basic Anatomy Review

**Figure 3. Midline cross-section of abdominal wall**

**Figure 4. Blood supply to the GI tract**

**Venous Flow**

- **Azygos vein**
- **Esophageal vein**
- **Liver**
- **Stomach**
- **Umbilicus**
- **Inferior vena cava**
- **Superior mesenteric vein**
- **Paraumbilical vein**
- **Middle colic vein**
- **Left colic veins**
- **Sigmoid veins**
- **Sigmoid colon**
- **Superior rectal vein**
- **Middle rectal veins**
- **Inferior rectal vein**
- **Appendix**

**Porto-systemic anastomoses:**
1. Esophageal branches of left gastric vein with esophageal veins
2. Paraumbilical veins with subcutaneous veins of anterior abdominal wall
3. Superior rectal vein with middle and inferior rectal veins

**Figure 5. Venous drainage of the GI tract**

- **Celiac trunk (1)**
  - i) Common hepatic artery (2)
  - • Hepatic proper (3)
  - • Left hepatic artery (4)
  - • Right hepatic artery (5)
  - • Gastroduodenal (8)
  - ii) Left gastric artery (6)
  - iii) Splenic artery (9)

- **Superior mesenteric artery (10)**
  - i) Right colic artery (12)
  - ii) Middle colic artery (11)
  - iii) Ileocolic artery (13)
  - iv) Ileal and jejunal branches (14)

- **Inferior mesenteric artery (15)**
  - i) Left colic artery (16)
  - ii) Sigmoid arteries (17)
  - iii) Superior rectal artery (18)

- **Organ Arteries**
  - **Liver**
  - Left and right hepatic (branches of hepatic proper)
  - **Spleen**
  - Splenic
  - **Gallbladder**
  - Cystic (branch of right hepatic artery)
  - **Stomach**
  - 1. Lesser curvature: right and left gastric
  - 2. Greater curvature: right (branch of gastroduodenal) and left (branch of splenic)
  - 3. Fundus: short gastrics (branch of spleen)
  - **Duodenum**
  - 1. Gastroduodenal
  - 2. Pancreaticoduodenals (superior branch of gastroduodenal, inferior branch of superior mesenteric)
  - **Pancreas**
  - 1. Pancreatic branches of splenic
  - 2. Pancreaticoduodenals
  - **Small intestine**
  - 1. Superior mesenteric branches: jejunal, ileal, ileocolic
  - **Large intestine**
  - 1. Superior mesenteric branches: right colic, middle colic
  - 2. Inferior mesenteric branches: left colic, sigmoid, superior rectal
Differential Diagnoses of Common Presentations

Acute Abdominal Pain

- acute abdomen = severe abdominal pain of acute onset and requires urgent medical attention
- in patients with acute abdominal pain, the first diagnoses that you should consider are those requiring potential urgent surgical intervention
- two main patterns constituting urgent general surgery referrals are peritonitis and obstruction

Table 1. Differential Diagnosis of Acute Abdominal Pain

</table>

In all patients presenting with an acute abdomen, order the following:

**KEY TESTS FOR SPECIFIC DIAGNOSIS**
- Liver function tests (LFTs) including ALP, ALT, AST, bilirubin
- Amylase/lipase
- Urinalysis
- β-hCG (in women of childbearing age)
- Troponins
- Lactate

**KEY TESTS FOR OR PREPARATION**
- CBC, electrolytes, BUN, creatinine, glucose
- CXR + ECG
- PT/INR and PTT

Pancreatitis can look like a surgical abdomen, but is rarely an indication for immediate laparotomy

Localization of Pain
- Most digestive tract pain is perceived in the midline because of bilaterally symmetric innervation. Kidney, ureter, ovary, or somatically innervated structures are more likely to cause lateralized pain

Referred Pain
- Biliary colic: to right shoulder or scapula
- Renal colic: to groin
- Appendicitis: periumbilical to right lower quadrant (RLQ)
- Pancreatitis: to back
- Ruptured aortic aneurysm: to back or flank
- Perforated ulcer: to RLQ (via right paracolic gutter)
- Hip pain: to groin

Most Common Presentations of Surgical Pain
- Sudden onset with rigid abdomen = perforated viscus
- Pain out of proportion to physical findings = mesenteric ischemia or ischemic bowel
- Vague pain that subsequently localizes = appendicitis or other intra-abdominal process that irritates the parietal peritoneum
- Waves of colicky pain = bowel obstruction

Types of Peritonitis
- Primary peritonitis: spontaneous without clear etiology
- Secondary peritonitis: due to a perforated viscus
- Tertiary peritonitis: recurrent secondary peritonitis more often with resistant organisms
Abdominal Mass

Table 2. Differential Diagnosis of Abdominal Mass

Gastrointestinal Bleeding

- see Gastroenterology.

**Indications for Surgery**

- failure of medical management
- exsanguinating hemorrhage: hemodynamic instability despite vigorous resuscitation
- recurrent hemorrhage after initial stabilization procedures (up to two attempts of endoscopic control)
- hypovolemic shock
- prolonged bleeding with transfusion requirement >4 units
- bleeding at rate >1 unit/h

**Surgical Management of GI Bleeding**

- **UGIB**
  - bleeding from a source proximal to the ligament of Treitz
  - often presents with hematemesis and melena unless very brisk (then can present with hematochezia, hypotension, tachycardia)
  - initial management with endoscopy; if fails, then consider surgery
  - note: PUD accounts for approximately 55% of severe UGIB

- **LGIB**
  - bleeding from a source distal to the ligament of Treitz
  - often presents with BRBPR unless proximal to transverse colon
  - may occasionally present with melena
  - initial management with colonoscopy to detect and potentially stop source of bleeding
  - 75% of patients will spontaneously stop bleeding, however if bleeding continues barium enema should NOT be performed
  - angiography, RBC scan to determine source as indicated
  - surgery indicated if bleeding is persistent - aimed at removing underlying cause of bleeding
  - obscure bleed may require blind total colectomy if the source is not found

**Table 3. Differential Diagnosis of GI Bleeding**

*Managed surgically in most cases

Jaundice

- see Gastroenterology, G41

Pre-Operative Preparations

Considerations
- informed consent (see Ethical, Legal, and Organizational Medicine, ELOAMS)
- screening questionnaire to assess important potential risk factors such as age, exercise capacity, medication use, and allergies
- consults: anesthesia, medicine, as indicated
- NPO for ≥ 6 h prior, activity as tolerated (AAT), vital signs routine (VSR)
- IV – balanced crystalloid at maintenance rate (4:2:1 rule → roughly 100-125 cc/h): normal saline or Ringer’s lactate; bolus to catch up on estimated losses including losses from bowel prep
- appropriate use of fluids perioperatively decreases risk of cardiorespiratory complications
- review patient’s regular medications including prednisone: consider pre-operative stress dose if prednisone with β-blocker used in past year
- prophylactic antibiotics depending on wound class (within 1 h prior to incision); usually cefazolin (Ancef®) ± metronidazole (Flagyl®)
- consider bowel prep: cleans out bowel and decreases bacterial population
- oral cathartic (e.g. fleet Phosphosoda®) starting previous day
- use in selected cases; current evidence does not support routine use
- consider DVT prophylaxis for all inpatient surgery (heparin)
- do not hold heparin prior to surgery unless epidural is expected
- hold clopidogrel and coumadin 5 to 7 days pre-operative; consider holding ASA (surgeon dependent)
- smoking cessation x 8 wk or more pre-operative can significantly decrease post-operative complications
- remote infection: delay elective surgery until infection controlled

Investigations
- routine pre-operative laboratory investigations for elective procedures should be selective
  - only ASA class and surgical risk have been found to independently predict post-operative adverse effects
- blood components: group and screen or cross and type depending on procedure
- CBC, electrolytes, BUN, creatinine
- INR/PT, PTT
- ABGs and/or PFTs if predisposed to respiratory insufficiency
- CXR (PA and lateral) if >50 yr old or previously abnormal within past 6 mo
- ECG if >50 yr old or as indicated by history
- β-hCG testing in all women of reproductive age

Drains
- NGT
  - indications: gastric decompression, analysis of gastric contents, irrigation/dilution of gastric contents, to test anastomosis for leak, feeding (only if necessary due to risk of aspiration → naso-jejunal tube preferable)
Surgical Complications

- general principles in preventing complications during the post-operative period include:
  - frequent examination of the patient (daily or more) and their wound
  - removal of surgical tubes as soon as possible
  - early ambulation
  - monitor fluid balance and electrolytes
  - analgesia - enough to adequately address pain, but not excessive
  - skillful nursing care

Post-Operative Fever

- fever does not necessarily imply infection particularly in the first 24-48 h post-operative
- fever may not be present or is blunted if patient is receiving chemotherapy, glucocorticoids, or immunosuppression
- timing of fever may help identify cause
  - hours after surgery – POD #1 (immediate)
    - inflammatory reaction in response to trauma from surgery
    - reaction to blood products received during surgery
    - malignant hyperthermia
  - POD #1-2 (acute)
    - atelectasis (most common cause of fever in first 48 h after surgery)
    - early wound infection (especially Clostridium, Group A Streptococcus – feel for crepitus and look for “dishwater” drainage)
    - aspiration pneumonitis
    - other: Addisonian crisis, thyroid storm, transfusion reaction
  - POD #3-7 (subacute): infections more likely
    - UTI, surgical site infection, IV site/line infection, septic thrombophlebitis, leakage at bowel anastomosis (tachycardia, hypotension, oliguria, abdominal pain)
  - POD #8+ (delayed)
    - intra-abdominal abscess, DVT/PE (can be anytime post-operative, most commonly POD #8-10), drug fever
    - other: cholecystitis, peri-rectal abscess, URTI, infected seroma/biloma/hematoma, parotitis, C. difficile colitis, endocarditis, sinusitis (from nasogastric tube)

Treatment

- treat primary cause
- antipyrexia (e.g. acetaminophen)

WOUND CARE (see Plastic Surgery, PL8)

- can shower POD #2-3 (epithelialization of wound occurs within 48 h)
- dressings can generally be removed POD #2 and left uncovered if dry (check with attending to be sure)
- examine wound if wet dressing, signs of infection (fever, tachycardia, pain)
- skin sutures and staples can be removed POD #7-10
  - exceptions: incision crosses crease (groin), closed under tension, in extremities (hand) or patient factors (elderly, corticosteroid use, immunosuppressed) removed POD #14, earlier if signs of infection
- negative pressure dressings consist of foam and suction, promote granulation
  - ideal for large (grafted sites) or non-healing wounds (irradiated skin, ulcer)

DRAINS

- sometimes placed intraoperatively to prevent fluid accumulation (blood, pus, serum, bile, urine)
- can be used to assess quantity of third space fluid accumulation post-operatively
- potential route of infection, bring out through separate incision (vs. operative wound) to decrease risk of wound infection and remove as soon as possible
• types of drains
  - open (e.g. Penrose), higher risk of infection
  - closed: 1) Gravity drainage (e.g. Foley catheter); 2) Underwater-seal drainage system (e.g. chest tube); 3) Suction drainage (e.g. Jackson-Pratt)
  - sump (e.g. NGT)
• monitor drain outputs daily
• drains should be removed once drainage is minimal (<30-50 cc/24 h)
• evidence does not support routine post-operative drainage of abdominal cavity
• drains do not guarantee that the patient will not form a collection of fluid
• ridged drains can erode through internal structures, and excessive suction can cause necrosis

SURGICAL SITE INFECTION

Etiology
• S. aureus, E. coli, Enterococcus, Streptococcus spp., Clostridium spp.

Risk Factors

Table 4. Procedures and Their Impact on Surgical Site Infection

<table>
<thead>
<tr>
<th>Classification</th>
<th>Clean</th>
<th>Clean-Contaminated</th>
<th>Contaminated</th>
<th>Dirty/Infected</th>
</tr>
</thead>
<tbody>
<tr>
<td>Definition</td>
<td>Incision under sterile conditions; nontraumatic; no entrance of hollow organ</td>
<td>Incision under sterile conditions; ENTRANCE of hollow viscus; no evidence of active infection; minimal contamination</td>
<td>Incision under sterile conditions; MAJOR contamination of wound during procedure (i.e. gross spillage of stool, infection in biliary, respiratory, or GU systems)</td>
<td>Established infection present before wound is made in skin</td>
</tr>
<tr>
<td>Example</td>
<td>Wound created to repair hernia</td>
<td>Routine cholecystectomy; colon resection</td>
<td>Bowel obstruction with enterotomy and spillage of contents; necrotic bowel resection; fresh traumatic wounds</td>
<td>Appendiceal abscess; traumatic wound with contaminated devitalized tissue; perforated viscus</td>
</tr>
<tr>
<td>Infection Rate</td>
<td>&lt;2%</td>
<td>3-4%</td>
<td>7-10%</td>
<td>30-40%</td>
</tr>
<tr>
<td>Wound Closure</td>
<td>Primary closure</td>
<td>Primary closure</td>
<td>Often secondary closure</td>
<td>Secondary closure</td>
</tr>
</tbody>
</table>

• patient characteristics
  - age, DM, steroids, immunosuppression, obesity, burn, malnutrition, patient with other infections, traumatic wound, radiation, chemotherapy
  - other factors
    - prolonged pre-operative hospitalization, reduced blood flow, break in sterile technique, multiple antibiotics, hematoma, seroma, foreign bodies (drains, sutures, grafts), skin preparation, hypoxemia, hypothermia

Clinical Presentation
• typically fever POD #5-8 (Streptococcus and Clostridium can present in 24 h)
• pain, blanchable wound erythema, induration, purulent discharge, warmth
• complications: fistula, sinus tracts, sepsis, abscess, suppressed wound healing, superinfection, spreading infection to myonecrosis or fascial necrosis (necrotizing fasciitis), wound dehiscence, evisceration, hernia

Prophylaxis
• used to reduce the chance of surgical site infections
  - pre-operative antibiotics for most surgeries (cefazolin ± metronidazole or if β-lactam allergy, clindamycin ± gentamycin)
    - within 1 h pre-incision; can re-dose at 1-2 half-lives (~q4-8h) in the OR
    - not required for low risk elective cholecystectomy, hemorrhoidectomy, fistulotomy, sphincterotomy for fissure
    - generally no need to continue prophylactic antibiotics post-operatively
    - reserve post-operative antibiotics for treatment of suspected or documented intra-abdominal infection
  - normothermia (maintain patient temperature 96.8-100.4ºF during OR)
  - hyperoxegenation (consider FiO2 of 80% in OR)
  - chlorhexidine-alcohol wash of surgical site
  - hair removal should not be performed unless necessary; if so, clipping superior to shaving
  - protect skin edges (moistened lap pads); consider delayed primary closure of incision for contaminated wounds

Treatment
• examination of the wound: inspect, compress adjacent areas, swab drainage for C&S and Gram stain
• re-open affected part of incision, drain, pack, heal by secondary intention in most cases
• for deeper infections, debride necrotic and non-viable tissue
• antibiotics and demarcation of erythema only if cellulitis or immunodeficiency
WOUND HEMORRHAGE/HEMATOMA
- secondary to inadequate surgical control of hemostasis

Risk Factors
- anticoagulant therapy, coagulopathies, thrombocytopenia, DIC, severe liver disease, myeloproliferative disorders, severe arterial HTN, severe cough
- more common with transverse incisions through muscle

Clinical Features
- pain, swelling, discoloration of wound edges, leakage
- rapidly expanding neck hematoma can compromise airway and is a surgical emergency (consider opening wound at bedside)

Treatment
- pressure dressing
- open drainage ± wound packing (large hematoma only)
- if significant bleeding, may need to re-operate to find source (often do not find a discrete vessel)

SEROMA
- fluid collection other than pus or blood
- secondary to transection of lymph vessels
- delays healing
- increased infection risk

Treatment
- pressure dressing ± needle drainage
- if significant may need to re-operate

WOUND DEHISCENCE
- disruption of fascial layer, abdominal contents contained by skin only
- 95% caused by intact suture tearing through fascia

Clinical Features
- typically POD #1-3; most common presentation sign is serosanguinous or salmon-colored drainage from wound ± evisceration
- palpation of wound edge: should normally feel a “healing ridge” from abdominal wall closure (raised area of tissue under incision)

Risk Factors
- local: technical failure of closure, increased intra-abdominal pressure (e.g. COPD, ileus, bowel obstruction), hematoma, infection, poor blood supply, radiation, patient not fully paralyzed while closing, transverse incision
- systemic: smoking, malnutrition (hypalbuminemia, vitamin C deficiency), connective tissue diseases, immunosuppression, pulmonary disease, ascites, poor nutrition, steroids, chemotherapy, obesity, other (e.g. age, sepsis, uremia)
- DM alone is not a risk factor

Treatment
- place moist dressing over wound with binder around abdomen and transfer to OR
- may consider conservative management with debridement of fascial and/or skin margins

EVISCERATION
- protrusion of abdominal viscera through the abdominal wall
- also known as ‘burst abdomen’, is a surgical emergency (mortality rates as high as 45%)

Treatment
- take patient for operative closure, use slowly absorbable suture ± retention sutures

Urinary and Renal Complications

URINARY RETENTION
- may occur after any operation with general anesthesia or spinal anesthesia
- more likely in older males with history of benign prostatic hyperplasia, patients on anticholinergics

Clinical Presentation
- abdominal discomfort, palpable bladder, overflow incontinence, post-void residual urine volume >100 mL
Treatment
• Foley catheter to rest bladder, then trial of voiding

OLIGURIA/ANURIA (see Nephrology, NP33)

Etiology
• prerenal vs. renal vs. postrenal
  ▪ most common post-operative cause is prerenal ± ischemic ATN
  ▪ external fluid loss: hemorrhage, dehydration, diarrhea
  ▪ internal fluid loss: third-spacing due to bowel obstruction, pancreatitis

Clinical Presentation
• urine output <0.5 cc/kg/h, increasing Cr, increasing BUN

Treatment
• according to underlying cause; fluid deficit is treated with crystalloid (NS or RL)

Post-Operative Dyspnea

• see Respiratory Complications below and Cardiac Complications, GS11

Etiology
• respiratory: atelectasis, pneumonia, pulmonary embolus (PE), ARDS, asthma, pleural effusion
• cardiac: MI, arrhythmia, CHF
• inadequate pain control

Respiratory Complications

ATELECTASIS
• comprises 90% of post-operative pulmonary complications

Clinical Features
• low-grade fever on POD #1, tachycardia, crackles, decreased breath sounds, bronchial breathing, tachypnea

Risk Factors
• COPD, smoking, obesity, elderly persons
• upper abdominal/thoracic surgery, oversedation, significant post-operative pain, poor inspiratory effort

Treatment
• pre-operative prophylaxis
  ▪ smoking cessation (best if >8 wk pre-operative)
  ▪ provide incentive spirometer and instruct how to use
• post-operative prophylaxis
  ▪ incentive spirometry, deep breathing exercise, chest physiotherapy, intermittent positive-pressure breathing
  ▪ selective NGT decompression after abdominal surgery
  ▪ short-acting neuromuscular blocking agents
  ▪ minimize use of respiratory depressive drug, good pain control, early ambulation

PNEUMONIA/PNEUMONITIS
• may be secondary to aspiration of gastric contents during anesthetic induction or extubation, causing a chemical pneumonitis

Risk Factors
• aspiration: general anesthetic, decreased LOC, GERD, full stomach, bowel/gastric outlet obstruction + non-functioning NGT, pregnancy, seizure disorder
• non-aspiration: atelectasis, immobility, pre-existing respiratory disease

Clinical Features
• productive cough, fever
• tachycardia, cyanosis, respiratory failure, decreased LOC
• CXR: pulmonary infiltrate

Treatment
• prophylaxis: see atelectasis prophylaxis, pre-operative NPO/NGT, rapid sequence anesthetic induction
• immediate removal of debris and fluid from airway
• consider endotracheal intubation and flexible bronchoscopic aspiration
• IV antibiotics to cover oral nosocomial aerobes and anaerobes (e.g. ceftriaxone, metronidazole)
PULMONARY EMBOLUS (see Respirology, R18)

Clinical Features
- unilateral leg swelling and pain (DVT as a source of PE), sudden onset shortness of breath, tachycardia, fever
- most commonly POD #8-10, but can occur anytime post-operatively

Treatment
- IV heparin, long-term warfarin (INR = 2-3) for 3 mo
- Greenfield (IVC) filter if contraindications to anticoagulation or develops a complication while on anticoagulation
- prophylaxis: subcutaneous heparin (5,000 U bid) or LMWH, compression stockings (TED™ Hose)

PULMONARY EDEMA

Etiology
- cardiogenic vs. noncardiogenic
- circulatory overload: excess volume replacement, LV failure, shift of fluid from peripheral to pulmonary vascular bed, negative airway pressure, alveolar injury due to toxins (e.g. ARDS)
  - more common with pre-existing cardiac disease
- negative pressure pulmonary edema due to inspiratory efforts against a closed glottis upon awakening from general anesthesia

Clinical Features
- shortness of breath, crackles at lung bases, CXR abnormal

Treatment (LMNOP)
- Lasix
- Morphine (decreases symptoms of dyspnea, venodilator and afterload reduction)
- Nitrates (venodilator)
- Oxygen + non-invasive ventilation
- Position (sit patient up)

RESPIRATORY FAILURE

Clinical Features
- dyspnea, cyanosis, evidence of obstructive lung disease
- earliest manifestations – tachypnea and hypoxemia (RR >25, pO2 <60)
- pulmonary edema, unexplained decrease in SaO2

Treatment
- ABCs, O2, ± intubation
- bronchodilators, diuretics to treat CHF
- adequate blood pressure to maintain pulmonary perfusion
- if these measures fail to keep PaO2 >60, consider ARDS

Cardiac Complications

- abnormal ECGs common in post-operative period (compare to pre-operative ECG)
- common arrhythmias: supraventricular tachycardia, atrial fibrillation (secondary to fluid overload, PE, MI)

MYOCARDIAL INFARCTION

- see Cardiology and Cardiac Surgery, C27
- surgery increases risk of MI
  - incidence
  - 0.5% in previously asymptomatic men >50 yr old
  - 40-fold increase in men >50 yr old with previous MI

Risk Factors
- pre-operative HTN, CHF
- previous MI (highest risk ≤6 mo, but risk never returns to baseline)
- increased age
- intraoperative hypotension
- operations >3 h
- angina

Clinical Features
- majority of cases on day of operation or POD #3-4 (shifting of third space fluid back into intravascular compartment)
- often silent without chest pain, may only present with new-onset CHF (dyspnea), arrhythmias, hypotension
Intra-Abdominal Abscess

Definition
• collection of pus walled-off from rest of peritoneal cavity by inflammatory adhesions and viscera

Etiology
• usually polymicrobial: Gram-negative bacteria, anaerobes
  • consider Gram-positives if coexisting cellulitis

Risk Factors
• emergency, contaminated OR
• GI surgery with anastomoses
• risk factors for poor healing (DM, poor nutrition, etc.)
• may occur POD #3 after laparotomy when third space fluid re-distribution occurs

Clinical Features
• persistent spiking fever, dull pain, weight loss
• mass difficult to palpate
• peritoneal signs if abscess perforation and secondary peritonitis
• leukocytosis or leukopenia (immunocompromised, elderly)
• co-existing effusion (pleural effusion with subphrenic abscess)
• common sites: pelvis, Morrison’s pouch (space between kidney and liver), subphrenic, paracolic gutters, lesser sac, peri-appendiceal, post-surgical anastomosis, diverticular, psoas

Investigations
• CBC, blood cultures x2
• CT ± water-soluble contrast
• DRE (pelvic abscess)

Treatment
• eradication (preferred), laparoscopy, open drainage
• subsequent antibiotic coverage, ciprofloxacin (Cipro®) + metronidazole (Flagyl®)

Paralytic Ileus
• see Bowel Obstruction, GS24

Delirium
• see Psychiatry, PS16 and Neurology, N19

Thoracic Surgery

Hiatus Hernia

Figure 6. Types of hiatus hernia
SLIDING HIATUS HERNIA (Type I)

- see Figure 6
- herniation of both the stomach and the gastroesophageal (GE) junction into thorax
- 90% of esophageal hernias

Risk Factors
- age
- increased intra-abdominal pressure (e.g. obesity, pregnancy, coughing, heavy lifting)
- smoking

Clinical Features
- majority are asymptomatic
- larger hernias frequently associated with GERD (60-80%) due to decreased competence of the LES

Complications
- most common complication is GERD
- other complications are rare and are related to reflux
  - esophagitis (dysphagia, heartburn)
  - consequences of esophagitis (peptic stricture, Barrett’s esophagus, esophageal carcinoma)
  - extra-esophageal complications (pneumonitis/pneumonia, asthma, cough, laryngitis)

Investigations
- CXR, barium swallow, endoscopy, or esophageal manometry (technique for measuring LES pressure)
- 24-48 h esophageal pH monitoring to quantify reflux
- gastroscopy with biopsy to document type and extent of tissue damage and rule out esophagitis, Barrett’s esophagus, and cancer

Treatment
- lifestyle modification
  - stop smoking, weight loss, elevate head of bed, no meals <3 h prior to sleeping, smaller and more frequent meals, avoid alcohol, coffee, mint, and fat
  - medical
    - antacid, H₂-antagonist, PPI, prokinetic agent
  - surgical (<15%)
    - if failure of medical therapy, esophageal stricture, severe nocturnal aspiration, Barrett’s esophagus
    - anti-reflux procedure (usually laparoscopic) e.g. Nissen fundoplication
      - fundus of stomach is wrapped around the lower esophagus and sutured in place
      - 90% success rate at experienced centers

PARAESOPHAGEAL HIATUS HERNIA (Type II)

- see Figure 6
- herniation of all or part of the stomach through the esophageal hiatus into the thorax with an undisplaced GE junction
- least common esophageal hernia (<10%)

Clinical Features
- usually asymptomatic due to normal GE junction
- pressure sensation in lower chest, dysphagia

Complications
- hemorrhage, incarceration, strangulation (gastric volvulus), obstruction, gastric stasis ulcer (Cameron lesions – causes Fe-deficiency anemia)

Treatment
- surgery to prevent severe complications
  - reduce hernia and excise hernia sac, repair defect at hiatus, and anti-reflux procedure (e.g. Nissen fundoplication)
  - may consider suturing stomach to anterior abdominal wall (gastropyexy)
  - in very elderly patients at high surgical risk consider PEG (percutaneous endoscopic gastrostomy)

MIXED HIATUS HERNIA (Type III)

- see Figure 6
- combination of Types I and II

TYPE IV HERNIA
- herniation of other abdominal organs into thorax: colon, spleen, small bowel
Esophageal Perforation

**Etiology**
- iatrogenic (most common)
  - endoscopic, dilatation, biopsy, intubation, operative, NGT placement
  - barogenic
    - trauma
    - repeated, forceful vomiting (Boerhaave’s syndrome)
    - other: convulsions, defecation, labor (rare)
  - ingestion injury
    - foreign body, corrosive substance
  - carcinoma

**Clinical Features**
- neck or chest pain
- fever, tachycardia, hypotension, dyspnea, respiratory compromise
- subcutaneous emphysema, pneumothorax, hematemesis

**Investigations**
- CXR: pneumothorax, pneumomediastinum, pleural effusion, subdiaphragmatic air
- CT chest: widened mediastinum, pneumomediastinum
- contrast swallow (water-soluble then thin barium): contrast extravasation

**Treatment**
- supportive if rupture is contained
  - NPO, vigorous fluid resuscitation, broad-spectrum antibiotics, possible percutaneous drainage
- surgical
  - <24 h
    - primary closure of a healthy esophagus or resection of diseased esophagus
  - >24 h or non-viable wound edges
    - diversion and exclusion followed by delayed reconstruction (i.e. cervical esophagostomy (“spit fistula”) proximally, close esophagus distally, gastrostomy/jejunostomy tube for decompression/feeding)

**Complications**
- sepsis, abscess, fistula, empyema, mediastinitis, death
- post-operative esophageal leak
- mortality 10-50% dependent on timing of diagnosis

Esophageal Carcinoma

**Epidemiology**
- M:F = 3:1
- onset 50-60 yr of age
- upper (20-33%), middle (33%), lower (33-50%)
- main types:
  - most common worldwide: SCC in upper 2/3 of esophagus
  - most common in Western countries: adenocarcinoma in distal 1/3 of esophagus

**Risk Factors**
- geographic variation in incidence
- SCC
  - underlying esophageal disease such as strictures, diverticula, achalasia
  - smoking, alcohol, hot liquids, pickled foods (high in nitrosamines)
  - more common in patients from Asia
- adenocarcinoma
  - Barrett’s esophagus (most important), smoking, obesity (increased reflux), GERD

**Clinical Features**
- frequently asymptomatic; late presentation
- progressive dysphagia (mechanical): first solids then liquids
- odynophagia then constant pain
- constitutional symptoms
- regurgitation and aspiration (aspiration pneumonia)
- hematemesis, anemia
- tracheoesophageal or bronchoesophageal fistula
- direct, hematogenous, or lymphatic spread
  - trachea (coughing), recurrent laryngeal nerves (hoarseness, vocal paralysis), aorta, pericardium, liver, lung, bone, celiac, and mediastinal nodes

**Perioperative Chemo(radio)therapy vs. Primary Surgery for Resectable Adenocarcinoma of the Stomach, Gastroesophageal Junction, and Lower Esophagus**

**Study**: Review of RCTs to examine the effect of perioperative chemotherapy for gastroesophageal adenocarcinoma on survival and other clinically relevant outcomes.

**Results/Conclusions**: 14 RCTs, 2,422 participants.

1. Perioperative chemotherapy was associated with a significantly longer overall survival (HR 0.81, 95% CI 0.73-0.89), a relative survival increase of 19% and an absolute increase of 9%.
2. Tumors of the GE junction showed a more pronounced response to perioperative chemotherapy compared to other sites.
3. Combined chemoradiotherapy was more effective for tumors of the esophagus and GE junction compared to chemotherapy alone.
4. Perioperative chemotherapy was more effective in younger patients and is associated with longer disease-free survival, higher rates of R0 resection, and a more favorable tumor stage upon resection.
5. Resection with negative margins is a strong predictor of survival.
Investigations
- barium swallow: shows narrowing – suggestive but not diagnostic
- esophagoscopy: biopsy and assess resectability
- endoscopic ultrasound (EUS)
  - visualize local disease
  - regional nodal involvement (most accurate way to stage the cancer) ± FNA
- bronchoscopy ± thoracoscopy
  - rule out airway invasion in tumors of the upper and mid esophagus
- full metastatic workup (CT head, CT chest/abdomen/pelvis, LFTs, etc.)

Treatment
- if present with distant metastatic disease
  - treat with systemic therapy and palliate symptoms (esophageal stent)
- if locally advanced (locally invasive disease or nodal disease on CT or EUS)
  - multimodal therapy
    - concurrent external beam radiation and chemotherapy (cisplatin and 5-FU)
    - possibility of curative esophagectomy after chemoradiation if disease responds well
    - if unable to tolerate multimodal therapy or if highly advanced disease, consider palliative resection, brachytherapy, or endoscopic dilatation/stenting/laser ablation for palliation
- if early stage (non-transmural and without evidence of nodal disease)
  - esophagectomy (transhiatal or trans-thoracic approach) and lymphadenectomy
  - anastomosis in chest or neck
  - stomach most often used for reconstruction; may also use colon
  - neoadjuvant chemotherapy and radiation are controversial
  - adjuvant chemotherapy ± radiation usually recommended for post-operative node-positive disease
- more advanced stages
  - neoadjuvant chemotherapy ± radiation followed by esophagectomy

Prognosis
- prognosis usually poor because presentation is usually at advanced stage (5 yr survival for all stages is only 17%)

OTHER DISORDERS
- esophageal varices (see Gastroenterology, G26)
- Mallory-Weiss tear (see Gastroenterology, G27)

Pleur, Lung, and Mediastinum
- see Respirology, R22

Tube Thoracostomy

Indications
- to drain abnormal large-volume air or fluid collections in the pleural space
  - pleural effusion, hemothorax, chylothorax, empyema
  - pneumothorax, if
    - large or progressive
    - patient is on mechanical ventilation
    - bronchopleural fistula
    - tension pneumothorax
- to treat symptomatic and/or recurrent pleural effusion
  - see Respirology, R24
  - for long-term drainage of malignant effusions
  - via facilitation of pleurodesis (obliteration of the pleural space by instilling talc or doxycycline to cause fibrosis and adherence of parietal and visceral pleura)

Complications
- overall complications are rare (1-3%)
- malposition (most common complication), especially by inexperienced operators:
  - tubes may dissect along the external chest wall, or may be placed below the diaphragm
- bleeding (anticoagulation is a relative contraindication)
- local infection, empyema
- perforation of lung parenchyma
- risk of re-expansion pulmonary edema when large volumes of air or fluid are drawn off quickly (>1.0-1.5 L)

Figure 7. Typical thoracic surgery incisions

Figure 8. Tube thoracostomy
Lung Transplantation

Conditions Leading to Transplantation
- chronic acquired lung disease: COPD
- genetic: CF, emphysema due to α-1 antitrypsin deficiency
- idiopathic interstitial pneumonias: IPF, nonspecific interstitial pneumonitis
- HTN-related: IPAH, secondary pulmonary HTN, Eisenmenger’s syndrome
- other: sarcoidosis, lymphangioleiomyomatosis, pulmonary Langerhans cell histiocytosis

Clinical Indications
- transplantation should be considered for patients with advanced lung disease refractory to maximal medical or surgical therapy
- patients who are symptomatic during activities of daily living and limited expected survival over the next 2 yr

Criteria for Transplantation
- lung allocation score based on: 1) post-transplant survival measure, and 2) waiting list urgency measure
- transplant benefit = post-transplant survival (days) – waitlist survival (days)

Contraindications
- uncontrolled or untreatable pulmonary or extrapulmonary infection
- malignancy in the last 2 yr
- advanced cardiopulmonary disease
- significant chest wall/spinal deformity
- active cigarette smoking
- HIV infection, ongoing HBV or HCV infections

Post-Operative Complications
- primary graft dysfunction: main cause is ischemia-reperfusion injury, graded by PaO2/FiO2 ratio and CXR findings
- airway anastomotic complications (focal infection, bronchial necrosis and dehiscence, excess granulation tissue, tracheobronchomalacia, stenosis, fistula)
- chronic graft dysfunction: bronchiolitis obliterans syndrome
- infectious complications (bacterial, fungal, CMV, community-acquired respiratory viruses, mycobacteria)
- malignancy (non-melanoma skin cancer, post-transplant lymphoproliferative disease, colon, breast, Kaposi’s sarcoma, bladder)

Prognosis
- median survival for all adult recipients: 5.4 yr
- 1 yr survival: COPD > IPF > IPAH
- 10 yr survival: CF, α-1 antitrypsin deficiency > IPAH > COPD, IPF

Chronic Obstructive Pulmonary Disease

- see Respirology, R9

Treatment
- indications for surgical management
  - dyspnea despite maximal medical therapy and pulmonary rehabilitation
  - CT showing hyperinflation and heterogeneously distributed emphysema predominant in the upper lung zone
  - may be used as a bridging procedure to lung transplantation
- contraindications
  - age >75, cigarette smoking within the prior 6 mo, higher risk of surgical mortality
  - homogeneously distributed emphysematous changes without areas of preserved lung tissue
  - diffusing capacity of lung for carbon monoxide <20% of predicted, PaCO2 >60 mmHg, PaO2 <45 mmHg
- surgical procedures
  - lung volume reduction surgery: wedge excision of emphysematous tissue
  - bilateral or unilateral, thoracotomy or VATS

Complications of Treatment
- air leak: may require reintubation and mechanical ventilation
- arrhythmias, pneumonia

Prognosis
- total mortality at 2 yr same as with maximal medical therapy, but better exercise capacity and quality of life with LVRS

Long-Term Survival Analysis of the Canadian Lung Volume Reduction Surgery Trial
Study: Retrospective observational study assessing the long-term survival of patients enrolled in the CLVRS at 8-10 yr follow-up.
Results/Conclusions: 62 patients total. 52 patients had a median survival time of 4.11 yr. Compared with the best medical care group, patients in the LVRS group showed a 16 mo survival advantage and a 20% reduction in mortality. LVRS may provide long-term benefits in the treatment of end-stage emphysema, however, the results were not statistically significant.
Peptic Ulcer Disease

GASTRIC ULCERS
- see Gastroenterology, G12

Indications for Surgery
- unresponsive to medical treatment (intractability)
  ▪ always operate if fails to heal completely, even if biopsy negative: could be primary gastric lymphoma or adenocarcinoma
- dysplasia or carcinoma
  ▪ always biopsy ulcer for malignancy
- hemorrhage: 3x greater risk of bleeding compared to duodenal ulcers
- complications: obstruction, perforation, bleeding
- surgical treatment is increasingly rare due to H. pylori eradication and medical treatment

Procedures
- distal gastrectomy with ulcer excision: Billroth I or Billroth II
- vagotomy and pyloroplasty only if acid hypersecretion (rare)
- wedge resection if possible or biopsy with primary repair

DUODENAL ULCERS
- see Gastroenterology, Bleeding Peptic Ulcer, G13, and Peptic Ulcer Disease, G12
- most within 2 cm of pylorus (duodenal bulb)

Indications for Surgery
- hemorrhage, rebleed in hospital, perforation, gastric outlet obstruction
  ▪ decision to operate based on amount of blood loss (usually >8 units), rate of bleeding, and hemodynamic stability
- intractable despite medical management (endoscopy)

Procedures
- Graham patch of perforated ulcer-plication of ulcer and omental patch
- oversewing of bleeding ulcer ± pyloroplasty
- pyloroplasty, gastroduodenostomy, or gastrojejunostomy (improved drainage)
- antrectomy (eliminate hormonal stimulation from the antrum)
- gastric resection (decrease the number of parietal cells)
- vagotomy
  ▪ rarely done now due to H. pylori eradication and PPI

Complications of Surgery
- retained antrum
- fistula (gastrocolic/gastrojejunal)
- dumping syndrome, postvagotomy diarrhea, afferent loop syndrome (see Complications of Gastric Surgery, GS20)

### Gastric Carcinoma

#### Epidemiology
- **M:F = 3:2**
- incidence of adenocarcinoma < 10 (US) vs. 60 (Japan, Korea) per 100,000 (incidence highest in Asia and Latin America)
- most common age group = 50-59 yr
- incidence has decreased by 2/3 in past 50 yr

#### Risk Factors
- *H. pylori*, causing chronic atrophic gastritis
- hereditary nonpolyposis colorectal cancer (HNPCC), hereditary diffuse gastric carcinoma (HDGC)
- smoking, alcohol, smoked food, nitrosamines
- pernicious anemia associated with achlorhydria and chronic atrophic gastritis
- gastric adenomatous polyps
- previous partial gastrectomy (>10 yr post-gastrectomy)
- hypertrophic gastropathy
- blood type A

#### Clinical Features
- clinical suspicion
  - ulcer fails to heal
  - lesion on greater curvature of stomach or cardia
  - asymptomatic, insidious, or late onset of symptoms
  - postprandial abdominal fullness, vague epigastric pain
  - anorexia, weight loss
  - burping, N/V, dyspepsia, dysphagia
  - hepatomegaly, epigastric mass (25%)
  - hematemesis, fecal occult blood, melena, iron-deficiency anemia
- metastasis:
  - peritoneum, liver, lung, brain

#### Investigations
- OGD and biopsy; EUS to assess pre-operative T-stage and N-stage
- CT chest/abdomen/pelvis CT (for metastatic workup see Table 7)
Table 6. TNM Classification System for Staging of Gastric Carcinoma (AJCC/IUCC 2010)

</tbody>
</table>

Treatment
- adenocarcinoma
  - proximal lesions
    - total gastrectomy and Roux-en-Y esophagojejunostomy
  - distal lesions
    - distal gastrectomy or subtotal gastrectomy: wide (5-6 cm) margins, en bloc removal of omentum and lymph nodes
- palliation
  - gastric resection to decrease bleeding and relieve obstruction, enables the patient to eat
  - radiation therapy
  - studies are showing larger role for chemotherapy

Gastrointestinal Stromal Tumor

Epidemiology
- most common mesenchymal neoplasm of GI tract
- derived from interstitial cells of Cajal (cells associated with Auerbach's plexus that have autonomous pacemaker function which coordinate peristalsis throughout the GI tract)
- 75-80% associated with tyrosine kinase (c-KIT) mutations
- most common in stomach (50%) and proximal small intestine (25%), but can occur anywhere along GI tract
- typically present with vague abdominal mass, feeling of abdominal fullness, or with secondary symptoms of bleeding and anemia
- often discovered incidentally on CT, laparotomy, or endoscopy

Risk Factors
- Carney's triad: GISTs, paraganglioma, and pulmonary chondroma
- Type IA neurofibromatosis

Investigations
- EUS is helpful
- pre-operative biopsy: controversial, but useful for indeterminate lesions:
  - not recommended if index of suspicion for GIST is high
  - percutaneous biopsy is NOT recommended due to high friability and risk of peritoneal spread

Treatment
- surgical resection if >2 cm; follow with serial endoscopy if <2 cm and resect if growing or symptomatic
- localized GIST
  - surgical resection with preservation of intact pseudocapsule
  - lymphadenectomy NOT recommended, as GISTs rarely metastasize to lymph nodes
  - consider imatinib post-operative for high-risk GIST (large, >4 cm with significant mitotic activity)
- advanced disease (i.e. metastases to liver and/or peritoneal cavity)
  - chemotherapy with imatinib
Prognosis
• risk of metastatic potential depends on
  ▪ tumor size (worse if >10 cm)
  ▪ mitotic activity (worse if >5 mitotic figures or 50/hpf)
  ▪ degree of nuclear pleomorphism
  ▪ location: with identical sizes, extra-gastric location has a higher risk of progression than GISTs in the stomach
• metastases to liver, omentum, peritoneum; nodal metastases rare

Bariatric Surgery
• weight reduction surgery for morbid obesity
• indications: BMI >40 or BMI >35 with related comorbidity (e.g. DM, CAD, sleep apnea, HTN, severe joint disease)
• requires multidisciplinary evaluation and follow-up

Surgical Options
• malabsorptive/restrictive
  ▪ laparoscopic Roux-en-Y gastric bypass (most common – see Figure 9)
  ▪ staple off small gastric pouch (restrictive) with Roux-en-Y limb to pouch (malabsorptive) with dumping syndrome physiology
  ▪ most effective, higher complication rates
• restrictive
  ▪ laparoscopic adjustable gastric banding
    ▪ silicone band around fundus creates pouch, adjustable through port under skin
  ▪ laparoscopic sleeve gastrectomy
    ▪ resects most of the greater curvature (about 75% of the stomach); becoming popular weight-loss procedure
• malabsorptive
  ▪ biliopancreatic diversion with duodenal switch
  ▪ gastrectomy, enteroenterostomy, duodenal division closure and duodenoenterostomy

Complications
• perioperative mortality ~1% (anastomotic leak with peritoneal signs, PE)
• obstruction at enteroenterostomy (see Complications of Gastric Surgery, below)
• staple line dehiscence
• internal hernias
• dumping syndrome
• cholelithiasis due to rapid weight loss (20-30%)
• band abscess (if long-term)

Complications of Gastric Surgery
• most resolve within 1 yr

Alkaline Reflux Gastritis (see Figure 10A)
• duodenal contents (bilious) reflux into stomach causing gastritis ± esophagitis
• treatment
  ▪ medical: H₂-blocker, metoclopramide, cholestyramine (bile acid sequestrant)
  ▪ surgical: conversion of Billroth I or II to Roux-en-Y

Afferent Loop Syndrome (see Figure 10B)
• accumulation of bile and pancreatic secretions causes intermittent mechanical obstruction and distention of afferent limb
• clinical features
  ▪ early postprandial distention, RUQ pain, nausea, bilious vomiting, anemia
• treatment: surgery (conversion to Roux-en-Y increases afferent loop drainage)

Dumping Syndrome (see Figure 10C)
• early (~15 min post-prandial)
  ▪ etiology
    ▪ hyperosmotic chyme released into small bowel (fluid accumulation and jejunal distention)
  ▪ clinical features
    ▪ post-prandial symptoms
    ▪ epigastric fullness or pain, emesis, nausea, diarrhea, palpitations, dizziness, tachycardia, diaphoresis
Blind-Loop Syndrome (see Figure 10D)
- bacterial overgrowth of colonic Gram-negative bacteria in afferent limb
- clinical features
  - anemia/weakness, diarrhea, malnutrition, abdominal pain, and hypocalcemia
- treatment: broad-spectrum antibiotics, surgery (conversion to Billroth I)

Postvagotomy Diarrhea (see Figure 10E)
- up to 25%
- bile salts in colon inhibit water resorption
- treatment: medical (cholestyramine), surgical (reversed interposition jejunal segment)

Small Intestine

Tumors of Small Intestine

BENIGN TUMORS
- 10x more common than malignant
- usually asymptomatic until large
- most common sites: terminal ileum, proximal jejunum
- polyps
  - adenomas
  - hamartomas
  - FAP (see Familial Colon Cancer Syndromes, GS33)
- juvenile polyps
- other: leiomyomas, lipomas, hemangiomas

Carcinoid Syndrome Symptoms – FDR
- Flushing
- Diarrhea
- Right-sided heart failure
Abdominal Hernia

**Definition**
- defect in abdominal wall causing abnormal protrusion of intra-abdominal contents

**Epidemiology**
- M:F = 9:1
- lifetime risk of developing a hernia: males 20-25%, females 2%
- frequency of occurrence: 50% indirect inguinal, 25% direct inguinal, 8-10% incisional (ventral), 5% femoral, 3-8% umbilical
- most common surgical disease of males

**Risk Factors**
- activities which increase intra-abdominal pressure
  - obesity, chronic cough, asthma, COPD, pregnancy, constipation, bladder outlet obstruction, ascites, heavy lifting
- congenital abnormality (e.g. patent processus vaginalis, indirect inguinal hernia)
- previous hernia repair, especially if complicated by wound infection
- loss of tissue strength and elasticity (e.g. hiatus hernia, aging, repetitive stress)

**Clinical Features**
- mass of variable size
- tenderness worse at end of day, relieved with supine position or with reduction
- abdominal fullness, vomiting, constipation
- transmits palpable impulse with coughing or straining

**Investigations**
- physical examination usually sufficient
- ultrasound ± CT (CT required for obturator hernias, internal abdominal hernias and Spigelian and/or femoral hernias in obese patients)

**Classification**
- complete: hernia sac and contents protrude through defect
- incomplete: partial protrusion through the defect
- internal hernia: sac herniating into or involving intra-abdominal structure
- external hernia: sac protrudes completely through abdominal wall
- strangulated hernia: vascular supply of protruded viscus is compromised (ischemia)
  - requires emergency repair
- incarcerated hernia: irreducible hernia, not necessarily strangulated
- Richter’s hernia: only part of bowel circumference (usually anti-mesenteric border) is incarcerated or strangulated so may not be obstructed
  - a strangulated Richter’s hernia may self-reduce and thus be overlooked, leaving a gangrenous segment at risk of perforation in the absence of obstructive symptoms
- sliding hernia: part of wall of hernia sac formed by retroperitoneal structure (usually colon)

**Anatomical Types**
- groin
  - indirect and direct inguinal, femoral (see Figure 13)
  - pantaloon: combined direct and indirect hernias, peritoneum draped over inferior epigastric vessels
- epigastrium: defect in linea alba above umbilicus
- incisional: ventral hernia at site of wound closure, may be secondary to wound infection
- other: Litter’s (involving Meckel’s), Amyand’s (containing appendix), lumbar, obturator, peristomal, umbilical, Spigelian (ventral hernia through linea semilunaris), Grynfeltt-Lesshaft hernia (superior lumbar hernia), Petit’s hernia (inferior lumbar triangle)
Combinations
• incarceration
• strangulation
  ▪ small, new hernias more likely to strangulate
  ▪ femoral >> indirect inguinal > direct inguinal
  ▪ intense pain followed by tenderness
  ▪ intestinal obstruction, gangrenous bowel, sepsis
  ▪ surgical emergency
• DO NOT attempt to manually reduce hernia if septic or if contents of hernial sac gangrenous
  ▪ will cause closed loop SBO – and EMERGENCY

Treatment
• surgical treatment (herniorrhaphy) is only to prevent strangulation and evisceration, for
  symptomatic relief, for cosmesis, if asymptomatic can delay surgery
• repair may be done open or laparoscopic and may use mesh for tension-free closure
• most repairs are now done using tension-free techniques – a plug in the hernial defect and a
  patch over it or patch alone
• observation is acceptable for small asymptomatic inguinal hernias

Post-Operative Complications
• recurrence (15-20%)
  ▪ risk factors: recurrent hernia, age >50, smoking, BMI >25, poor pre-operative functional status
    (ASA ≥3 – see Anesthesia, A3), associated medical conditions: type 2 DM, hyperlipidemia,
    immunosuppression, any comorbid conditions increasing intra-abdominal pressure
  ▪ less common with mesh/”tension-free” repair
• scrotal hematoma (3%)
• painful scrotal swelling from compromised venous return of testes
• deep bleeding: may enter retroperitoneal space and not be initially apparent
• difficulty voiding
• nerve entrapment
  ▪ ilioinguinal (causes numbness of inner thigh or lateral scrotum)
  ▪ genital branch of genitofemoral (in spermatic cord)
• stenosis/occlusion of femoral vein
• acute leg swelling
• painful scrotal swelling from compromised venous return of testes
• groin pain following surgical repair
• acute leg swelling

Watchful Waiting vs. Repair of Inguinal Hernia in Minimally Symptomatic Men: A Randomized Clinical Trial

JAMA 2019;321:292-292
Purpose: To compare pain and the physical component score (PCS) of the Short Form-36 Version 2 survey at 2 yr in men with minimally symptomatic inguinal hernias treated with watchful waiting or surgical repair.
Methods: 917 of 170 men (n=364 watchful waiting, n=553 surgical repair) followed up for 2-4.5 yr. Watchful-waiting patients were followed up at 6 mo and annually and watched for hernia symptoms; repair patients received standard open tension-free repair and were followed up at 3 and 6 mo and annually. The main outcome was pain and discomfort interfering with usual activities at 2 yr and change in PCS from baseline to 2 yr. Secondary outcomes were complications, patient-reported pain, functional status, activity levels, and satisfaction with care.
Results: Primary intention-to-treat outcomes were similar at 2 yr for watchful waiting vs. surgical repair: pain limiting activities (5.1% vs. 2.2%, respectively; p=0.06 [corrected]; PCS (improvement over baseline, 0.29 points vs. 0.13 points; p=0.79). Twenty-three percent of patients assigned to watchful waiting crossed over to receive surgical repair (increase in hernia-related pain was the most common reason offered; 17% assigned to receive repair crossed over to watchful waiting. Self-reported pain in watchful-waiting patients crossing over improved after repair. Occurrence of post-operative hernia-related complications was similar in patients who received repair vs assigned and in watchful-waiting patients who crossed over. One watchful-waiting patient (0.7%) experienced acute hernia incarceration without strangulation within 2 yr; a second had acute incarceration with bowel obstruction at 4 yr, with a frequency of 1.6/1,000 patient/yr inclusive of patients following up for as long as 4.5 yr.
Conclusion: Watchful waiting is an acceptable option for men with minimally symptomatic inguinal hernias. Delays surgical repair until symptoms increase is safe because acute hernia incarcerations occur rarely.
**Bowel Obstruction**

**Definition**
- partial or complete blockage of the bowel resulting in failure of intestinal contents to pass through lumen

**Pathogenesis**
- disruption of the normal flow of intestinal contents leading to proximal dilatation and distal decompression
- may take 12-24 h to decompress, therefore passage of feces and flatus may occur after the onset of obstruction
- bowel ischemia may occur if blood supply is strangulated or if bowel wall inflammation leads to venous congestion
- bowel wall edema and disruption of normal bowel absorptive function can lead to increased intraluminal fluid and transudative fluid loss into peritoneal cavity, electrolyte disturbances

**Risk Factors**
- prior abdominal or pelvic surgery, abdominal wall or groin hernia, history of malignancy, prior radiation

**Differential Diagnosis**
- SBO, ILBO, pseudo-obstruction

**Clinical Features**
- must differentiate between obstruction and ileus, and characterize obstruction as small vs. large bowel, acute vs. chronic, partial vs. complete (constipation vs. obstipation), strangulating vs. non-strangulating, and with vs. without perforation
- differentiation between small and large bowel obstruction is key as LBO is a surgical emergency and often requires early surgery to avoid perforation

**Table 10. Bowel Obstruction vs. Paralytic Ileus**

</tbody>
</table>

**Complications (of total obstruction)**
- strangulating obstruction (10% of bowel obstructions) = surgical emergency
  - cramping pain turns to continuous ache, hematemesis, melena (if infarction)
  - fever, leukocytosis, tachycardia
  - peritoneal signs, early shock
  - see Intestinal Ischemia, GS28
- other
  - perforation; secondary to ischemia and luminal distention
  - sepsisemia
  - hypovolemia (due to third spacing)

**Investigations**
- radiological
  - upright CXR or left lateral decubitus to rule out free air, usually seen under the right hemidiaphragm
  - abdominal x-ray (3 views) to determine SBO vs. LBO vs. ileus
    - if ischemic bowel look for: free air, pneumatoasis, thickened bowel wall, air in portal vein, dilated small and large bowels, thickened or hose-like haustra (normally finger-like projections)
other
- most used: CT provides information on level of obstruction, severity, cause
  - important to rule out closed loop obstruction, especially in the elderly
- less used: upper GI series/small bowel series for SBO (if no cause apparent, i.e. no hernias, no previous surgeries)
- if suspect LBO, consider a rectal water-soluble (Gastrografin® for PO/PR; Hypaque® for IV) enema rather than barium enema (can thicken and cause complete obstruction)
- may consider ultrasound or MRI in pregnant patients

• laboratory
  - may be normal early in disease course
  - BUN, creatinine, hematocrit to assess degree of dehydration
  - fluid, electrolyte abnormalities
  - amylase elevated
  - metabolic alkalosis due to frequent emesis
  - if strangulation: leukocytosis with left shift, lactic acidosis, elevated LDH (late signs)

Treatment
- stabilize vitals, fluid and electrolyte resuscitation
- NGT to relieve vomiting, prevent aspiration, and decompress small bowel by prevention of further distention by swallowed air
- Foley catheter to monitor ins/outs

### Small Bowel Obstruction

**Etiology**

<table>
<thead>
<tr>
<th>Intraluminal</th>
<th>Intramural</th>
<th>Extramural</th>
</tr>
</thead>
<tbody>
<tr>
<td>Intussusception</td>
<td>Crohn’s</td>
<td>Adhesions</td>
</tr>
<tr>
<td>Gallstones</td>
<td>Radiation stricture</td>
<td>Incarcerated hernia</td>
</tr>
<tr>
<td></td>
<td>Adenocarcinoma</td>
<td>Peritoneal carcinomatosis</td>
</tr>
</tbody>
</table>

**Treatment**
- consider whether complete or partial obstruction, ongoing or impending strangulation, location and cause
  - SBO with history of abdomen/pelvic surgery → conservative management (NGT decompression, GI rest, serial abdominal exams) → surgery if no resolution in 48-72 h or complications
  - complete SBO, strangulation → urgent surgery after stabilizing patient with fluid resuscitation
  - SBO with no previous surgery and no evidence of carcinomatosis → operate
  - trial of medical management may be indicated in Crohn’s, recurrent SBO, carcinomatosis
  - special case: early post-operative SBO (within 30 d of abdominal surgery) → prolonged trial of conservative therapy may be appropriate, surgery is reserved for complications such as strangulation

**Prognosis**
- mortality: non-strangulating <1%, strangulating 8% (25% if >36 h), ischemic = up to 50%

### Large Bowel Obstruction

**Etiology**

<table>
<thead>
<tr>
<th>Intraluminal</th>
<th>Intramural</th>
<th>Extramural</th>
</tr>
</thead>
<tbody>
<tr>
<td>Constipation</td>
<td>Adenocarcinoma</td>
<td>Volvulus</td>

<td></td>
</tr>
</tbody>
</table>

**Table 12. Common Causes of LBO**

- MUST DO
  - Rule out CRC in constipated patient
  - Send for TURP in patient with BPH (treat intra-abdominal HTN)

- Increased Risk of Perforation with Distention as seen on Abdomen Imaging
  - Small bowel ≥3 cm
  - Distal colon ≥6 cm
  - Proximal colon ≥9 cm
  - Cecum ≥12 cm

- Patients presenting with a SBO in setting of “virgin” abdomen should have surgery ASAP – EXCEPTION: malignant obstruction ASAP

- In a non-virgin abdomen – adhesional SBOs resolve spontaneously with NGT decompression 70% of time

- Top 3 Causes of SBO (in order)
  - ABC
    - Adhesions
    - Bulge (hernias)
    - Cancer (neoplasms)

- Causes of SBO
  - SHAVING
    - Stricture
    - Hernia
    - Adhesions
    - Volvulus
    - Intussusception/BID
    - Neoplasm
    - Gallstones
Clinical Features (unique to LBO)

- open loop (10-20%)  
  ▪ incompetent ileocecal valve allows relief of colonic pressure as contents reflux into ileum, therefore clinical presentation similar to SBO
- closed loop (80-90%) (dangerous)  
  ▪ competent ileocecal valve, resulting in proximal and distal occlusions  
  ▪ massive colonic distention → increased pressure in cecum → bowel wall ischemia → necrosis → perforation

Treatment

- surgical correction of obstruction (usually requires resection + temporary diverting colostomy)  
- volvulus requires sigmoidoscopic or endoscopic decompression followed by operative reduction if unsuccessful  
  ▪ if successful, consider sigmoid resection on same admission  
- cecal volvulus can be a true volvulus or a cecal ‘bascule’ (cecum folds anteriorly to the ascending colon producing a flap valve occlusion to cecal emptying) – both need surgical treatment

Prognosis

- overall mortality: 10%
- cecal perforation + feculent peritonitis: 20% mortality

Colonic Pseudo-Obstruction

Definition

- condition with symptoms of intestinal blockage without any physical signs of blockage  
- paralytic ileus of large bowel

Differential Diagnosis

- acute: toxic megacolon, trauma, post-operative (especially post orthopedic procedures with prolonged immobilization), neurologic disease, retroperitoneal disease, medications (narcotics, psychiatric)  
- chronic: neurologic disease (enteric, central, peripheral nervous system), scleroderma

Toxic Megacolon

Pathogenesis

- extension of inflammation into smooth muscle layer causing paralysis  
- damage to myenteric plexus and electrolyte abnormalities are not consistently found

Etiology

- inflammatory bowel disease (ulcerative colitis > Crohn’s disease)  
- infectious colitis: bacterial (C. difficile, Salmonella, Shigella, Campylobacter), viral (cytomegalovirus), parasitic (E. histolytica)

Clinical Features

- infectious colitis usually present for >1 wk before colonic dilatation  
- diarrhea ± blood (but improvement of diarrhea may portend onset of megacolon)  
- abdominal distention, tenderness, ± local/general peritoneal signs (suggest perforation)  
- triggers: hypokalemia, constipating agents (opioids, antidepressants, loperamide, anticholinergics), barium enema, colonoscopy

Diagnostic Criteria

- must have both colitis and systemic manifestations for diagnosis  
- radiologic evidence of dilated colon  
- three of: fever, HR >120, WBC >10.5, anemia  
- one of: fluid and electrolyte disturbances, hypotension, altered LOC

Investigations

- CBC (leukocytosis with left shift, anemia from bloody diarrhea), electrolytes, elevated CRP, ESR  
- metabolic alkalosis (volume contraction and hypokalemia) and hypoalbuminemia are late findings  
- AXR: dilated colon >6 cm (right > transverse > left), loss of haustra  
- CT: useful to assess underlying disease
Treatment
- NPO, NGT, stop constipating agents, correct fluid and electrolyte abnormalities, transfusion
- serial AXRs
- broad-spectrum antibiotics (reduce sepsis, anticipate perforation)
- aggressive treatment of underlying disease (e.g. steroids in IBD, metronidazole for *C. difficile*)
- indications for surgery (50% improve on medical management)
  - worsening or persisting toxicity or dilation after 48-72 h
  - severe hemorrhage, perforation
  - high lactate and WBC especially for *C. difficile*
- procedure: subtotal colectomy + end ileostomy (may be temporary, with second operation for re-anastomosis later)

Prognosis
- average 25-30% mortality

Paralytic Ileus

Pathogenesis
- temporary paralysis of the myenteric plexus

Associations
- post-operative, intra-abdominal sepsis, medications (opiates, anesthetics, psychotropics),
  electrolyte disturbances (Na⁺, K⁺, Ca²⁺), *C. difficile*, inactivity

Treatment
- NGT decompression, NPO, fluid resuscitation, correct causative abnormalities (e.g. sepsis,
  medications, electrolytes), consider TPN for prolonged ileus
- post-operative: gastric and small bowel motility returns by 24-48 h, colonic motility by 3-5 d
- current interest in novel therapies such as gum chewing and pharmacologic therapy (opioid
  antagonists)

Ogilvie's Syndrome

- acute pseudo-obstruction
- distention of colon without mechanical obstruction in distal colon
- arises in bedridden patients with serious extraintestinal illness or trauma
- exact mechanism unknown, likely autonomic motor dysregulation → possibly sympathetic
  deprivation to colon, unopposed parasympathetic tone, and interruption of sacral
  parasympathetic tone to distal bowel
- first presents with abdominal distention (>90%) ± tenderness
- later symptoms mimic true obstruction

Associations
- most common: trauma, infection, cardiac (MI, CHF)
- disability (long-term debilitation, chronic disease, bed-bound nursing home patients,
  paraplegia), drugs (narcotic use, laxative abuse, polypharmacy), other (recent orthopedic or
  neurosurgery, post-partum, electrolyte abnormalities including hypokalemia, retroperitoneal
  hematoma, diffuse carcinomatosis)

Investigations
- AXR: cecal dilatation – if diameter ≥12 cm, increased risk of perforation

Treatment
- treat underlying cause
- NPO, NGT
- decompression: rectal tube, colonoscopy, neostigmine (cholinergic drug), surgical
  decompression (ostomy/resection) uncommon
- surgery (extremely rare): if perforation, ischemia, or failure of conservative management

Prognosis
- most resolve with conservative management

Use caution when giving antidiarrheals, especially with bloody diarrhea
**Intestinal Ischemia**

**Etiology**
- **acute**
  - arterio-occlusive mesenteric ischemia (AOMI)
  - thrombotic, embolic, extrinsic compression (e.g. strangulating hernia)
  - non-occlusive mesenteric ischemia (NOMI)
  - mesenteric vasoconstriction secondary to systemic hypoperfusion (preserves supply to vital organs)
  - mesenteric venous thrombosis (MVT)
  - consider hypercoagulable state (i.e. rule out malignancy), DVT (prevents venous outflow)
- **chronic**: usually due to atherosclerotic disease – look for CVD risk factors

**Clinical Features**
- **acute**: severe abdominal pain out of proportion to physical findings, vomiting, bloody diarrhea, bloating, minimal peritoneal signs early in course, hypotension, shock, sepsis
- **chronic**: postprandial pain, fear of eating, weight loss
- **common sites**: SMA supplied territory, “watershed” areas of colon – splenic flexure, left colon, sigmoid colon

**Investigations**
- **laboratory**: leukocytosis (non-specific), lactic acidosis (late finding)
  - amylase, LDH, CK, ALP can be used to observe progress
  - hypercoagulability workup if suspect venous thrombosis
- **AXR**: portal venous gas, intestinal pneumatosis, free air if perforation
- **contrast CT**: thickened bowel wall, luminal dilatation, SMA or SMV thrombus, mesenteric/portal venous gas, pneumatosis
- **CT angiography** is the gold standard for acute arterial ischemia

**Treatment**
- fluid resuscitation, correct metabolic acidosis, NPO, NGT decompression of stomach, prophylactic broad-spectrum antibiotics, avoid vasoconstrictors and digitalis
- exploratory laparotomy
- angiogram, embolectomy/thrombectomy, bypass/graft, mesenteric endarterectomy, anticoagulation therapy, percutaneous transluminal angioplasty ± stent
- segmental resection of necrotic intestine
  - assess extent of viability; if extent of bowel viability is uncertain, a second look laparotomy 12-24 h later is mandatory

**Appendix**

**Appendicitis**

**Epidemiology**
- 6% of population, M>F
- 80% between 5-35 yr of age

**Pathogenesis**
- luminal obstruction → bacterial overgrowth → inflammation/swelling → increased pressure
  → localized ischemia → gangrene/perforation → localized abscess (walled off by omentum) or peritonitis
- **etiologies**
  - children or young adult: hyperplasia of lymphoid follicles, initiated by infection
  - adult: fibrosis/stricture, fecolith, obstructing neoplasm
  - other causes: parasites, foreign body

**Clinical Features**
- most reliable feature is progression of signs and symptoms
- low grade fever (38°C), rises if perforation
- abdominal pain then anorexia, N/V
- classic pattern: pain initially periumbilical; constant, dull, poorly localized, then well localized pain over McBurney’s point
  - due to progression of disease from visceral irritation (causing referred pain from structures of the embryonic midgut, including the appendix) to irritation of parietal structures
  - McBurney’s sign

**McBurney’s Sign**
Tenderness 1/3 the distance from the ASIS to the umbilicus on the right side
• perioperative management
  • conserve bowel: resect as little as possible to avoid short gut syndrome
  • can alleviate symptoms, address complications, improve quality of life

Principles of Surgical Management
  • see Gastroenterology, G19

ADENOCARCINOMA
  • see GS21

Treatment
  • hydrate, correct electrolyte abnormalities
  • surgery (gold standard, 20% mortality with perforation especially in elderly) + antibiotic coverage
  • if localized abscess (palpable mass or large phlegmon on imaging and often pain >4-5 d), consider radiologic drainage + antibiotics x 14 d ± interval appendectomy in 6 wk (controversial)
  • appendectomy
    • laparoscopic vs. open (see sidebar)
    • complications: spillage of bowel contents, pelvic abscess, enterocutaneous fistula
    • perioperative antibiotics:
      • cefazolin + metronidazole (no post-operative antibiotic unless perforated)
      • other choices: 2nd/3rd generation cephalosporin for aerobic gut organisms
  • colonoscopy in the elderly to rule out other etiology (neoplasm)

Prognosis
  • mortality rate: 0.08% (non-perforated), 0.5% (perforated appendicitis)

Tumors of the Appendix

CARCINOID TUMORS (most common type)
  • see Tumors of Small Intestine: Carcinoid, GS21

ADENOCARCINOMA
  • 50% present as acute appendicitis
  • spreads rapidly to lymph nodes, ovaries, and peritoneal surfaces
  • treatment: right hemicolecction

Inflammatory Bowel Disease

• see Gastroenterology, G19

Principles of Surgical Management
  • can alleviate symptoms, address complications, improve quality of life
  • conserve bowel: resect as little as possible to avoid short gut syndrome
  • perioperative management
    • optimize medical status: may require TPN (especially if >7 d NPO) and bowel rest
    • hold immunosuppressive therapy pre-operative, provide pre-operative stress dose of corticosteroid if patient had recent steroid therapy, taper steroids post-operative
    • DVT prophylaxis: heparin (IBD patients at increased risk of thromboembolic events)
**Crohn’s Disease**

- see Gastroenterology, G20

**Treatment**
- surgery is NOT curative, but over lifetime ~70% of Crohn’s patients will have surgery
- indications for surgical management
  - failure of medical management
  - SBO (due to stricture/inflammation): indication in 50% of surgical cases
  - abscess, fistula (enterocolic, vesicular, vaginal, cutaneous abscess), quality of life, perforation, hemorrhage, chronic disability, failure to thrive (children), perianal disease
- surgical procedures
  - resection and anastomosis/stoma if active or subacute inflammation, perforation, fistula
  - resection margin only has to be free of gross disease (microscopic disease irrelevant to prognosis)
  - stricturoplasty – widens lumen in chronically scarred bowel: relieves obstruction without resecting bowel (contraindicated in acute inflammation)

**Complications of Treatment**
- short gut syndrome (diarrhea, steatorrhea, malnutrition)
- fistulas
- gallstones (if terminal ileum resected, decreased bile salt resorption → increased cholesterol precipitation)
- kidney stones (loss of calcium in diarrhea → increased oxalate absorption and hyperoxaluria → stones)

**Prognosis**
- recurrence rate at 10 yr: ileocolic (25-50%), small bowel (50%), colonic (40-50%)
- re-operation at 5 yr: primary resection (20%), bypass (50%), stricturoplasty (10% at 1 yr)
- 80-85% of patients who need surgery lead normal lives
- mortality: 15% at 30 yr

**Ulcerative Colitis**

- see Gastroenterology, G22

**Treatment**
- indications for surgical management
  - failure of medical management (including inability to taper steroids)
  - complications: hemorrhage, obstruction, perforation, toxic megacolon (emergency), failure to thrive (children)
  - reduce cancer risk (1-2% risk per year after 10 yr of disease)
- surgical procedures
  - proctocolectomy and ileal pouch-anal anastomosis (IPAA) ± rectal mucosectomy (operation of choice)
  - proctocolectomy with permanent end ileostomy (if not a candidate for ileoanal procedures)
  - colectomy and IPAA ± rectal mucosectomy
- in emergency: total colectomy and ileostomy with Hartmann closure of the rectum, rectal preservation

**Complications of Treatment**
- early: bowel obstruction, transient urinary dysfunction, dehydration (high stoma output), anastomotic leak
- late: stricture, anal fistula/abscess, pouchitis, poor anorectal function, reduced fertility

**Prognosis**
- mortality: 5% over 10 yr
- total proctocolectomy will completely eliminate risk of cancer
- perforation of the colon is the leading cause of death from ulcerative colitis
Diverticular Disease

Definitions
- diverticulum: abnormal sac-like protrusion from the wall of a hollow organ
- diverticulosis: presence of multiple diverticula
- diverticulitis: inflammation of diverticula
- true (congenital) diverticuli: contain all layers of colonic wall, often right-sided
- false (acquired) diverticuli: contain mucosa and submucosa, often left-sided

![Diagram of true and false diverticuli](image)

Figure 15. Diverticular disease – cross-sections of true and false diverticuli

Diverticulosis

Epidemiology
- 5-50% of Western population, lower incidence in non-Western countries, M=F
- prevalence is age dependent: <5% by age 40, 30% by age 60, 65% by age 85
- 95% involve sigmoid colon (site of highest pressure)

Pathogenesis
- risk factors
  - lifestyle: low-fiber diet (predispose to motility abnormalities and higher intraluminal pressure) inactivity, obesity
  - muscle wall weakness from aging and illness (e.g. Ehler-Danlos, Marfan’s)
- high intraluminal pressures cause outpouching to occur at point of greatest weakness, most commonly where vasa recta penetrate the circular muscle layer, therefore increased risk of hemorrhage

Clinical Features
- uncomplicated diverticulosis: asymptomatic (70-80%)
- episodic abdominal pain (often LLQ), bloating, flatulence, constipation, diarrhea
- absence of fever/leukocytosis
- no physical exam findings or poorly localized LLQ tenderness
- complications
  - diverticulitis (15-25%): 25% of which are complicated (i.e. abscess, obstruction, perforation, fistula)
  - bleeding (5-15%): PAINLESS rectal bleeding, 30-50% of massive LGIB
  - diverticular colitis (rare): diarrhea, hematochezia, tenesmus, abdominal pain

Treatment
- uncomplicated diverticulosis: high fiber, education
- diverticular bleed
  - initially workup and treat as any LGIB
  - if hemorrhage does not stop, resect involved region

Diverticulitis

Epidemiology
- 95% left-sided in patients of Western countries, 75% right-sided in Asian populations

Pathogenesis
- erosion of the wall by increased intraluminal pressure or inspissated food particles → inflammation and focal necrosis → micro or macroscopic perforation
- usually mild inflammation with perforation walled off by pericolic fat and mesentery; abscess, fistula, or obstruction can ensue
- poor containment results in free perforation and peritonitis
Clinical Features
- depend on severity of inflammation and whether or not complications are present; hence ranges from asymptomatic to generalized peritonitis
- LLQ pain/tenderness (2/3 of patients) often for several days before admission
- constipation, diarrhea, N/V, urinary symptoms (with adjacent inflammation)
- complications (25% of cases)
  - abscess: palpable tender abdominal mass
  - fistula: colovesical (most common), colorectal, colovaginal, colocolonic
  - colonic obstruction: due to scarring from repeated inflammation
  - perforation: generalized peritonitis (feculent vs. purulent)
  - recurrent attacks rarely lead to peritonitis
- low-grade fever, mild leukocytosis common, occult or gross blood in stool rarely coexist with acute diverticulitis

Investigations
- AXR, upright CXR
  - localized diverticulitis (ileus, thickened wall, SBO, partial colonic obstruction)
  - free air may be seen in 30% with perforation and generalized peritonitis
- CT scan (test of choice): very useful for assessment of severity and prognosis; this is usually done with rectal contrast
  - 97% sensitive, 99% specific
  - increased soft tissue density within pericolic fat secondary to inflammation, diverticula secondary to inflammation, bowel wall thickening, soft tissue mass (pericolic fluid, abscesses), fistula
  - 10% of diverticulitis cannot be distinguished from carcinoma
- elective evaluations: establish extent of disease and rule out other diagnoses (polyps, malignancy) after resolution of acute episode
  - colonoscopy or barium enema and flexible sigmoidoscopy

Treatment
- uncomplicated: conservative management
- outpatient: clear fluids only until improvement and antibiotics (e.g. ciprofloxacin and metronidazole) 7-10 d to cover gram negative rods and anaerobes (e.g. B. fragilis)
- hospitalize: if severe presentation, inability to tolerate oral intake, significant comorbidities, fail to improve outpatient management
- treat with NPQ, IVF, IV antibiotics (e.g. IV ceftriaxone + metronidazole, ampicillin, gentamicin)
- indications for surgery
  - unstable patient with peritonitis
  - Hinchey stage 3-4
  - after 1 attack if immunosuppressed
  - consider after 2 or more attacks, recent trend is toward conservative management of recurrent mild/moderate attacks
- complications: generalized peritonitis, free air, abscess, fistula, obstruction, hemorrhage, inability to rule out colon cancer on endoscopy, or failure of medical management
- surgical procedures
  - for emergency or complex cases: Hartmann procedure: colon resection + colostomy and rectal stump + colostomy reversal in 3-6 mo
  - elective cases or minimal contamination of the abdominal cavity: consider colon resection + primary anastomosis

Prognosis
- mortality rates: 6% for purulent peritonitis, 35% for fecal peritonitis
- recurrence rates: 13-30% after first attack, 30-50% after second attack

Area of diverticulitis and inflammation

Colostomy

Resection of diseased area and closure of distal rectal stump

Anastomosis in approximately 3 mo
Colorectal Neoplasms

Colorectal Polyp

Definition
- polyp: protuberance into the lumen of normally flat colonic mucosa
- sessile (flat) or pedunculated (on a stalk)

Epidemiology
- 30% of the population have polyps by age 50, 40% by age 60, 50% by age 70

Clinical Features
- 50% in the rectosigmoid region, 50% are multiple
- usually asymptomatic, do not typically bleed, tenesmus, intestinal obstruction, mucus
- usually detected during routine endoscopy or familial/high risk screening

Pathology
- non-neoplastic
  - hyperplastic: most common non-neoplastic polyp
  - mucosal polyps: small <0.2 in, no clinical significance
  - inflammatory pseudopolyps: associated with IBD, no malignant potential
  - submucosal polyps: lymphoid aggregates, lipomas, leiomyomas, carcinoids
- neoplastic
  - hamartomas: juvenile polyps (large bowel), Peutz-Jegher syndrome (small bowel)
    - malignant risk due to associated adenomas (large bowel)
  - low malignant potential
    - most spontaneously regress or autoamputate
  - adenomas: premalignant, often carcinoma in situ
    - some may contain invasive carcinoma ("malignant polyp" – 3-9%): invasion into muscularis
    - malignant potential: villous > tubulovillous > tubular

Table 14. Characteristics of Tubular vs. Villous Polyps

Investigations
- colonoscopy is the gold standard for diagnosis and treatment of colonic polyps
- CT colonography; increasing in availability; patients still require bowel prep and will require colonoscopy if polyps are identified
- other: flexible sigmoidoscopy if polyps are detected, proceed to colonoscopy for examination of entire bowel and biopsy

Treatment
- indications: symptoms, malignancy or risk of malignancy (i.e. adenomatous polyps)
- endoscopic removal of entire growth
- surgical resection for those invading into muscularis (high risk of malignancy) and those too large to remove endoscopy
- follow-up endoscopy 1 yr later, then every 3-5 yr

Familial Colon Cancer Syndromes

FAMILIAL ADENOMATOUS POLYPOSIS

Pathogenesis
- autosomal dominant inheritance, mutation in adenomatous polyposis coli (APC) gene on chromosome 5q21

Clinical Features
- hundreds to thousands of colorectal adenomas usually by age 20 (by 40s in attenuated FAP)
- extracolonic manifestations
  - carcinoma of small bowel (i.e. polyps in colon), bile duct, pancreas, stomach, thyroid, adrenal, small bowel
  - congenital hypertrophy of retinal pigment epithelium presents early in life in 2/3 of patients; 97% sensitivity
  - virtually 100% lifetime risk of colon cancer (because of number of polyps)
Hereditary non-polyposis colorectal cancer – Lynch syndrome

Pathogenesis
- Autosomal dominant inheritance, mutation in a DNA mismatch repair gene (MSH2, MSH6, MLH1) resulting in microsatellite genomic instability and subsequent mutations
  - Microsatellite instability account for approximately 15% of all colorectal cancers

Clinical Features
- Early age of onset, right > left colon, synchronous and metachronous lesions
- Mean age of cancer presentation is 44 yr, lifetime risk 70-80% (M>F)
  - HNPCC I: hereditary site-specific colon cancer
  - HNPCC II: cancer family syndrome – high rates of extracolonic tumors (endometrial, ovarian, hepatobiliary, small bowel)

Diagnosis
- Amsterdam Criteria
  - 3 or more relatives with verified Lynch syndrome associated cancers, and 1 must be 1st degree relative of the other 2
  - 2 or more generations involved
  - 1 case must be diagnosed before 50 yr old
  - FAP is excluded
- Genetic testing (80% sensitive) – colonoscopy mandatory even if negative
  - Refer for genetic screening individuals who fulfill EITHER the Amsterdam Criteria (as above) OR the revised Bethesda Criteria (see sidebar)
- Colonoscopy (starting age 20) annually
- Surveillance for extracolonic lesions

Treatment
- Total colectomy and ileorectal anastomosis with annual proctoscopy

• Variants
  ▪ Gardner’s syndrome: FAP + extraintestinal lesions (sebaceous cysts, osteomas, desmoid tumors)
  ▪ Turcot syndrome: FAP + CNS tumors (childhood cerebellar medulloblastoma)

Investigations
- Genetic testing (80-95% sensitive, 99-100% specific)
- If no polyposis found: annual flexible sigmoidoscopy from puberty to age 50, then routine screening
- If polyposis or APC gene mutation found: annual colonoscopy and consider surgery (see Figure 16); consider upper endoscopy to evaluate for periampullary tumors

Treatment
- Surgery indicated by age 17-20
- Total proctocolectomy with ileostomy or total colectomy with ileorectal anastomosis
- Doxorubicin-based chemotherapy
- NSAIDs for intra-abdominal desmoids

HEREDITARY NON-POLYPOSIS COLORECTAL CANCER – LYNCH SYNDROME

Pathogenesis
- Autosomal dominant inheritance, mutation in a DNA mismatch repair gene (MSH2, MSH6, MLH1) resulting in microsatellite genomic instability and subsequent mutations

Clinical Features
- Early age of onset, right > left colon, synchronous and metachronous lesions
- Mean age of cancer presentation is 44 yr, lifetime risk 70-80% (M>F)
  - HNPCC I: hereditary site-specific colon cancer
  - HNPCC II: cancer family syndrome – high rates of extracolonic tumors (endometrial, ovarian, hepatobiliary, small bowel)

Diagnosis
- Amsterdam Criteria
  - 3 or more relatives with verified Lynch syndrome associated cancers, and 1 must be 1st degree relative of the other 2
  - 2 or more generations involved
  - 1 case must be diagnosed before 50 yr old
  - FAP is excluded
- Genetic testing (80% sensitive) – colonoscopy mandatory even if negative
  - Refer for genetic screening individuals who fulfill EITHER the Amsterdam Criteria (as above) OR the revised Bethesda Criteria (see sidebar)
- Colonoscopy (starting age 20) annually
- Surveillance for extracolonic lesions

Treatment
- Total colectomy and ileorectal anastomosis with annual proctoscopy

Colorectal Carcinoma

Epidemiology
- 4th most common cancer (after lung, prostate, and breast), 2nd most common cause of cancer death

Risk Factors
- Most patients have no specific risk factors
- Age >50 (dominant risk factor in sporadic cases), mean age is 70
- Genetic: FAP, HNPCC, family history of CRC
- Colonic conditions
  - adenomatous polyps (especially if >1 cm, villous, multiple)
  - IBD (especially UC: risk is 1-2%/yr if UC >10 yr)
  - Previous colorectal cancer (also gonadal or breast)
- Diet (increased fat, red meat, decreased fiber) and smoking
- DM and acromegaly (insulin and IGF-1 are growth factors for colonic mucosal cells)

Pathogenesis
- Adenoma-carcinoma sequence; rarely arise de novo

Revised Bethesda Criteria for HNPCC and Microsatellite Instability (MSI)
- Tumors from individuals should be tested for MSI in the following situations
  - Colorectal cancer diagnosed in a patient who is <50 yr
  - Presence of synchronous, metachronous colorectal, or other HNPCC-associated tumors, regardless of age
  - Colorectal cancer with the MSI-H histology diagnosed in a patient who is <60 yr
  - Colorectal cancer diagnosed in one or more first-degree relatives with an HNPCC-related tumor, with one of the cancers being diagnosed <50 yr
  - Colorectal cancer diagnosed in two or more first- or second-degree relatives with HNPCC-related tumors, regardless of age

Elderly persons who present with iron-deficiency anemia should be investigated for colon cancer

Referral Criteria for Genetic Screening for APC
- To confirm the diagnosis of FAP (in patients with ≥100 colorectal adenomas)
- To provide pre-symptomatic testing for individuals at risk for FAP (1st degree relatives who are ≥10 yr old)
- To confirm the diagnosis of attenuated FAP (in patients with ≥20 colorectal adenomas)
Clinical Features
- often asymptomatic
- hematochezia/melena, abdominal pain, change in bowel habits
- others: weakness, anemia, weight loss, palpable mass, obstruction
- 20% patients have distant metastatic disease at time of presentation
- spread
  - direct extension, lymphatic, hematogenous (liver most common, lung, bone, brain; tumor of distal rectum → IVC → lungs)
  - peritoneal seeding: ovary, Blumer’s shelf (pelvic cul-de-sac)

Table 16. TNM Classification System for Staging of Colorectal Carcinoma (AJCC/IUCC 2010)

- rectal cancer: pelvic MRI or endorectal ultrasound to determine T and N stage
- staging (see Table 16 and sidebar GS34): CT chest/abdomen/pelvis; bone scan, CT head only if laboratory: CBC, urinalysis, liver enzymes, liver function tests, carcinoembryonic antigen (CEA) (if a patient is FOBT +ve, or has microcytic anemia or has a change in bowel habits, do colonoscopy (best), look for synchronous lesions (3-5% of patients); alternative: air contrast enema)

</tbody>
</table>

Investigations
- colonoscopy (best), look for synchronous lesions (3-5% of patients); alternative: air contrast barium enema (“apple core” lesion) + sigmoidoscopy
- if a patient is FOBT +ve, or has microcytic anemia or has a change in bowel habits, do colonoscopy
- laboratory: CBC, urinalysis, liver enzymes, liver function tests, carcinoembryonic antigen (CEA) (for pre-operative baseline, >5/10/L have worse prognosis)
- staging (see Table 16 and sidebar GS34): CT chest/abdomen/pelvis; bone scan, CT head only if lesions suspected
- rectal cancer: pelvic MRI or endorectal ultrasound to determine T and N stage

Treatment
- colon cancer
  - wide surgical resection of lesion and regional lymphatic drainage; usually colectomy with primary anastomosis
  - curative: wide resection of lesion (2 in margins) with nodes and mesentery
  - palliative: if distant spread, local control for hemorrhage or obstruction
  - care is taken to not spread tumor by unnecessary palpation
  - cancer-bearing portion of colon is removed according to vascular distribution of segment
  - adjuvant chemotherapy (5-FU or oral capecitabine with oxaliplatin) can be considered for stages II or III
- rectal cancer
  - choice of operation depends on individual case; types of operations (see Figure 18)
  - low anterior resection of rectum (LAR): curative procedure of choice if adequate distal margins; uses technique of total mesorectal excision
  - abdominoperineal resection of rectum (APR): if adequate distal margins cannot be obtained; involves the removal of distal sigmoid colon, rectum, and anus – permanent end colostomy required
  - local excision: for select T1 lesions only
  - palliative procedures: electrocoagulation or laser photocoagulation for unresectable cancers for symptomatic relief
  - adjuvant therapy
    - combined neoadjuvant chemoradiation therapy followed by post-operative adjuvant chemotherapy for stages II and III

Follow-Up
- currently there are no data suggesting optimal follow-up
- combination of periodic CT chest/abdomen/pelvis, CEA, and colonoscopy is recommended
- CEA to monitor for initial response to treatment, and to assess for recurrence q3mo (not a screening test)
- intensive follow-up improves overall survival in low-risk patients

Table 17. Clinical Presentation of CRC

- spread
- 20% patients have distant metastatic disease at time of presentation
- others: weakness, anemia, weight loss, palpable mass, obstruction
- often asymptomatic

Follow-Up
- 10 yr incidence of local relapse was significantly lower in the pre-operative CRT group than in the post-operative group (7.1% vs. 10.1%, p=0.049)
- Overall survival at 10 yr was similar at ~60% for patients treated with pre-operative or post-operative CRT (p=0.35)
- Disease-free survival rates at 10 yr were similar at ~60% for patients treated with pre-operative or post-operative CRT (p=0.54)
- No significant difference was detected for 10 yr incidence of distant metastases (pre-operative CRT 23.9% vs. post-operative CRT 29.8%, p=0.19)

Conclusion: There is long-term reduction in local recurrence of stage II to III rectal cancer with pre-operative chemotherapy, but no improvement in overall survival or distant recurrence of disease.
**Angiodysplasia**

**Definition**
- vascular anomaly: focal submucosal venous dilatation and tortuosity

**Clinical Features**
- most frequently in right colon of patients >60 yr old
- bleeding typically intermittent, rarely massive, not usually hypotensive (melena, anemia, guaiac positive stools)

**Investigations**
- colonoscopy: cherry red spots, branching pattern from central vessel
- angiography: early-filling vein, vascular tuft, delayed emptying vein; rarely active bleeding
- RBC technetium-99 scan
- barium enema is contraindicated (obscures other x-rays, i.e. angiogram)

**Treatment**
- none if asymptomatic
- cautery, right hemicolectomy, embolization, vasopressin infusion, sclerotherapy, band ligation, laser, octreotide, and rarely segmental resection if other treatments fail

**Volvulus**

**Definition**
- rotation of segment of bowel about its mesenteric axis
- sigmoid (65%), cecum (30%), transverse colon (3%), splenic flexure (2%)
- 5-10% of large bowel obstruction; 25% of intestinal obstruction during pregnancy

**Risk Factors**
- age (50% of patients >70 yr: stretching/elongation of bowel with age is a predisposing factor)
- high fiber diet (can cause elongated/redundant colon), chronic constipation, laxative abuse, pregnancy, bedridden, institutionalization (less frequent evacuation of bowels)
- congenital hypermobile cecum

**Clinical Features**
- symptoms due to bowel obstruction (see Bowel Obstruction, GS24) or intestinal ischemia (see Intestinal Ischemia, GS28)
- colicky abdominal pain, persistence of pain between spasms, abdominal distention, vomiting

**Investigations**
- AXR (classic findings): "omega", "bent inner-tube", "coffee-bean" signs
- barium/Gastrografin" enema: "ace of spades" (or "bird’s beak") appearance due to funnel-like luminal tapering of lower segment towards volvulus
- sigmoidoscopy or colonoscopy as appropriate
- CT

**Treatment**
- initial supportive management (same as initial management for bowel obstruction (see Bowel Obstruction, GS24)
- cecum
  - nonsurgical
    - may attempt colonoscopic detorsion and decompression
  - surgical
    - right colectomy + ileotransverse colonic anastomosis
- sigmoid
  - nonsurgical
    - decompression by flexible sigmoidoscopy and insertion of rectal tube past obstruction
  - subsequent elective surgery recommended (50-70% recurrence)
  - surgical: Hartmann procedure (if urgent)
    - indications: strangulation, perforation, or unsuccessful endoscopic decompression
Fistula

Definition
• abnormal communication between two epithelialized surfaces (e.g. enterocutaneous, colovesical, aortoenteric, entero-enteric)

Etiology
• foreign object erosion (e.g. gallstone, graft)
• inflammatory states (e.g. infection, IBD [especially Crohn’s], diverticular disease)
• iatrogenic/surgery (e.g. post-operative anastomotic leak, radiation)
• congenital, trauma
• neoplastic

Investigations
• U/S, CT scan, fistulogram
• measure amount of drainage from fistula

Treatment
• decrease secretion: octreotide/somatostatin/omeprazole
• surgical intervention: dependent upon etiology (for non-closing fistulas); uncertainty of diagnosis

Stomas

Definition
• an opening of the GI tract onto the surface of the abdomen wall

Ileostomy
• usually positioned in RLQ; ileum is brought through rectus abdominus muscles
• indications: after protocolectomy for ulcerative colitis, in some cases of Crohn's disease or familial polyposis
• conventional ileostomy: discharges small quantities of liquid material continuously; appliance (plastic bag attached to a sheet of protective material) required at all times
• continent ileostomy: reservoir is constructed from distal ileum, emptied by inserting catheter into stoma several times a day; rarely used, has mostly been replaced by ileal pouch anal anastomosis

Colostomy
• indications: to decompress an obstructed colon, to protect a distal anastomosis after resection, or to evacuate stool after distal colon or rectum is removed
• colostomies can be done by making an opening in a loop of colon (loop colostomy) or by dividing the colon and bringing out one end (end colostomy)
• most common permanent colostomy is a sigmoid colostomy – expels stool once per day, no appliance required
• chronic paracolostomy hernia is a common complication

Complications (10%)
• obstruction: herniation, stenosis (skin and abdominal wall), adhesive bands, volvulus
• peri-ileostomy abscess and fistula
• skin irritation
• prolapse or retraction
• diarrhea (excessive output)
Anorectum

Hemorrhoids

Etiology
- vascular and connective tissue complexes form a plexus of dilated veins (cushion)
  - internal: superior hemorrhoidal veins, above dentate line, portal circulation
  - external: inferior hemorrhoidal veins, below dentate line, systemic circulation

Risk Factors
- increased intra-abdominal pressure: chronic constipation, pregnancy, obesity, portal HTN, heavy lifting

Clinical Features and Treatment
- internal hemorrhoids
  - engorged vascular cushions usually at 3, 7, 11 o'clock positions (patient in lithotomy position)
  - 1st degree: bleed but do not prolapse through the anus
    - treatment: high fiber/bulk diet, sitz baths, steroid cream, paroxime (Anusol®), rubber band ligation, sclerotherapy, photoacoagulation
  - 2nd degree: bleed, prolapse with straining, spontaneous reduction
    - treatment: rubber band ligation, photoacoagulation
  - 3rd degree: bleed, prolapse, requires manual reduction
    - treatment: same as 2nd degree, but may require closed hemorrhoidectomy
  - 4th degree: bleed, permanently prolapsed, cannot be manually reduced
    - treatment: closed hemorrhoidectomy
- external hemorrhoids
  - dilated venules usually mildly symptomatic
  - PAIN after bowel movement, associated with poor hygiene
  - medical treatment: dietary fiber, stool softeners, steroid cream (short course), paroxime (Anusol®), avoid prolonged straining
  - thrombosed hemorrhoids are very painful
  - resolve within 2 wk, may leave excess skin = perianal skin tag
  - treatment: consider surgical decompression within first 48 h of thrombosis, otherwise medical treatment

Anal Fissures

Definition
- tear of anal canal below dentate line (very sensitive squamous epithelium)
- 90% posterior midline, 10% anterior midline
- if off midline: consider other possible causes such as IBD, STDs, TB, leukemia, or anal carcinoma
- repetitive injury cycle after first tear:
  - sphincter spasm occurs preventing edges from healing and leads to further tearing
  - ischemia may ensue and contribute to chronicity

Etiology
- forceful dilation of anal canal: large, hard stools and irritant diarrheal stools
- tightening of anal canal secondary to nervousness/pain leads to further tearing
- others: habitual use of cathartics, childbirth

Clinical Features
- acute fissure
  - very painful bright red bleeding especially after bowel movement, sphincter spasm on limited DRE
  - treatment is conservative: stool softeners, bulking agent, sitz baths (heals 90%)
- chronic fissure (anal ulcer)
  - triad: fissure, sentinel skin tags, hypertrophied papillae

Always rule out more serious causes (e.g. colon CA) in a person with hemorrhoids and rectal bleeding
- treatment
  - stool softeners, bulking agents, sitz baths
  - topical nitroglycerin or nifedipine: increases local blood flow, promoting healing and relieves sphincter spasm
  - lateral internal anal sphincterotomy (most effective): objective is to relieve sphincter spasm → increases blood flow and promotes healing; but 5% chance of fecal incontinence therefore not commonly done
- alternative treatment
  - botulinum toxin: inhibits release of acetylcholine (ACh), reducing sphincter spasm

### Anorectal Abscess

#### Definition
- infection in one or more of the anal spaces
- usually bacterial infection of blocked anal gland at the dentate line
  - *E. coli, Proteus, Streptococci, Staphylococci, Bacteroides, anaerobes*

![Figure 22. Different types of perianal abscesses](image)

**Clinical Features**
- throbbing pain that may worsen with straining and ambulation
- abscess can spread vertically downward (perianal), vertically upward (supralevator), or horizontally (ischiorectal)
- tender perianal/rectal mass on exam

**Treatment**
- I&D
  - curative in 50% of cases
  - 50% develop anorectal fistulas
  - may require antibiotics if diabetic, heart murmur, or cellulitis

### Fistula-In-Ano

#### Definition
- anal fistula from rectum to perianal skin
- an inflammatory tract with internal os at dentate line, external os on skin

#### Etiology
- see *Fistula, GS37*
- same perirectal process as an anal abscess, therefore usually associated with an abscess
- other causes: post-operative, trauma, anal fissure, malignancy, radiation proctitis

**Clinical Features**
- intermittent or constant purulent discharge from perianal opening
- pain
- palpable cord-like tract
Treatment
- identification
  - internal opening
    - Goodsall’s rule
      - fistulas originating anterior to a transverse line through the anus will have a straight course and exit anteriorly, whereas those originating posterior to the transverse line will begin in the midline and have a curved tract
  - fistulous tract
    - probing or fistulography under anesthesia
- surgery
  - fistulotomy: unroof tract from external to internal opening, allow drainage, heals by secondary intention
  - low lying fistula (does not involve external sphincter) → primary fistulotomy
  - high lying fistula (involves external sphincter) → staged fistulotomy with Seton suture placed through tract
    - promotes drainage
    - promotes fibrosis and decreases incidence of incontinence
    - delineates anatomy
    - usually done to spare muscle cutting

Post-Operative
- sitz baths, irrigation, and packing to ensure healing proceeds from inside to outside

Complications
- recurrence
- rarely fecal incontinence

Pilonidal Disease
Definition
- chronic recurring abscess or chronic draining sinus in sacrococcygeal area

Epidemiology
- occurs most frequently in young men age 15-40 yr; rare in >50 yr

Etiology
- obstruction of the hair follicles in this area → formation of cysts, sinuses, or abscesses

Clinical Features
- asymptomatic until acutely infected, then pain/tenderness, purulent discharge, inspissated hair

Treatment
- acute abscess
  - I&D (often performed by primary care doctors)
  - wound packed open
  - 40% develop chronic pilonidal sinuses
- surgery
  - indication: failure of healing after I&D, recurrent disease, complex disease
  - pilonidal cystotomy: excision of sinus tract and cyst; wound closed by secondary intention, primary closure with tissue flap, or marsupialization (cyst edge sewn to surrounding tissue to leave sinus tract open)

Rectal Prolapse
Definition
- protrusion of some or all of rectal mucosa through external anal sphincter

Epidemiology
- extremes of ages: <5 yr old and >5th decade
- 85% women

Etiology
- lengthened attachment of rectum secondary to constant straining
- 2 types
  I. false/partial/mucosal: protrusion of mucosa only, radial furrows at junction with anal skin; most common type of rectal prolapse in childhood
  II. true/complete (most common): full thickness extrusion of rectal wall, concentric folds in:
    - first degree: prolapse includes mucocutaneous junction
    - second degree: without involvement of mucocutaneous junction
    - third degree (internal intussusception): prolapse is internal, concealed, or occult
Risk Factors
- gynecological surgery
- chronic neurologic/psychiatric disorders affecting motility

Clinical Features
- extrusion of mass with increased intra-abdominal pressure:
  - straining, coughing, laughing, Valsalva
- difficulty in bowel regulation:
  - tenesmus, constipation, fecal incontinence
- permanently extruded rectum with excoriation, ulceration, and constant soiling
- may be associated with urinary incontinence or uterine prolapse

Treatment
- Type I
  - conservative: gentle manual reduction of prolapsed area, especially in children
  - mucosectomy with excision of redundant mucosa, mostly in adults
- Type II
  - conservative: reduce if possible
  - surgery: abdominal, perineal, transsacral approaches

Anal Neoplasms

ANAL CANAL
Squamous Cell Carcinoma of Anal Canal (Above Dentate Line)
- most common tumor of anal canal (75%)
- anus prone to human papillomavirus (HPV) infection, therefore at risk for anal squamous intraepithelial lesions (ASIL)
  - high grade squamous intraepithelial lesion (HSIL) and low grade squamous intraepithelial lesion (LSIL) terminology used
- clinical features: anal bleeding, pain, mass, ulceration, pruritus; 25% asymptomatic
- treatment: chemotherapy ± radiation ± surgery
- prognosis: 80% 5 yr survival

Malignant Melanoma of Anal Canal
- 3rd most common site for primary malignant melanoma after skin, eyes
- aggressive, distant metastases common at time of diagnosis
- treatment: wide excision or APR ± chemoradiation
- prognosis: <5% 5 yr survival

ANAL MARGIN
- clinical features and treatment as for skin tumors elsewhere
- squamous and basal cell carcinoma, Bowen’s disease (SCC in situ), and Paget’s disease

Liver

<td>All complex, multiloculated cysts (except echinococcal) should be excised because of malignancy risk</td>
</tr>
<tr>
<td>Complications</td>
<td>Intracystic hemorrhage</td>
<td>Biliary cirrhosis, portal HTN, rupture, cholangiocarcinoma Abnormal pancreato胆管 junction is associated with increased risk of malignancy</td>
<td>Inferior vena cava compression rupture can cause biliary colic, jaundice, cholangitis, pancreatitis, or anaphylactic reaction</td>
<td>Cystadenocarcinoma can invade adjacent tissues and metastasize</td>
<td></td>
</tr>
</tbody>
</table>

Liver Abscesses

Etiology
- types
  - pyogenic (bacterial): most common etiology; most often polymicrobial – *E. coli, Klebsiella, Proteus, Strep. milleri*
  - parasitic (amoebic): *Entamoeba histolytica, Echinococcal cyst*
  - fungal: *Candida*
- sources: direct spread from biliary tract infection, portal spread from GI infection, systemic infection (e.g. endocarditis)

Clinical Features
- fever, malaise, chills, anorexia, weight loss, abdominal pain, nausea
- RUQ tenderness, hepatomegaly, jaundice

Investigations
- leukocytosis, anemia, elevated liver enzymes, hemagglutination titres for *Entamoeba* antibodies
- U/S, CXR (right basilar atelectasis/effusion), CT, cyst aspiration with C&S

Treatment
- treat underlying cause
- generally will treat initially with antibiotics alone and add surgical or percutaneous drainage and IV antibiotics for larger abscesses (initially ceftriaxone + metronidazole or pipercillin/tazobactam)
Prognosis
- overall mortality 15% – higher rate if delay in diagnosis, multiple abscesses, malnutrition

Neoplasms

Benign Liver Neoplasms

Hemangioma (cavernous)
- pathogenesis: most common benign hepatic tumor; results from malformation of angioblastic fetal tissue
- risk factors: F:M = 3:1
- clinical features
  - usually small and asymptomatic
  - consumptive coagulopathy if giant (in children)
- investigations
  - contrast CT (well-demarcated hypodense mass with peripheral enhancement and delayed venous emptying), U/S (homogenous hyperechoic mass), arteriography (rarely used; “cotton wool” appearance), MRI
  - biopsy may result in hemorrhage
- treatment
  - usually none unless tumor bleeds or is symptomatic, then excision by lobectomy or enucleation

Focal Nodular Hyperplasia
- pathogenesis: unclear, may be regenerative response to hyperperfusion from anomalous arteries at center of nodule
- risk factors: female, age 20-50
- clinical features: asymptomatic, rarely grows or bleeds, no malignant potential
- investigations: central stellate scar on CT scan; MRI, biopsy may be required
- treatment: may be difficult to distinguish from adenoma/fibrolamellar HCC (malignant potential) → often resected

Adenoma
- definition: benign glandular epithelial tumor
- risk factors: female, age 20-50, estrogen (OCP, pregnancy)
- clinical features: asymptomatic, 25% present with RUQ pain or mass, may present with bleeding
- investigations: CT (well-demarcated masses, often heterogeneous enhancement on arterial phase, isodense on venous phase without washout of contrast), U/S, MRI, biopsy often needed
- treatment
  - stop anabolic steroids or OCP
  - excise, especially if large (>5 cm), due to risk of transformation to hepatocellular carcinoma and spontaneous rupture/hemorrhage

Malignant Liver Neoplasms

Primary
- usually hepatocellular carcinoma (HCC)/hepatoma
- others include angiosarcoma, hepatoblastoma, hemangiendothelioma
- epidemiology: 3rd leading cause of cancer death worldwide, 9th in United States; highest in Africa, China, Taiwan
- risk factors
  - chronic liver inflammation: chronic hepatitis B (inherently oncogenic) and C, cirrhosis (especially macronodular), hemochromatosis, α1-antitrypsin deficiency
  - medications: OCPs (3x increased risk), steroids
  - smoking, alcohol, Betel nuts
  - chemical carcinogens ( aflatoxin, microcystin, vinyl chloride – associated with angiosarcoma)
- clinical features
  - RUQ discomfort, right shoulder pain
  - jaundice, weakness, weight loss, ± fever (if central tumor necrosis)
  - hepatomegaly, bruit, hepatic friction rub
  - ascites with blood (sudden intra-abdominal hemorrhage)
  - paraneoplastic syndromes – hypoglycemia, hypercalcemia, erythrocytosis, watery diarrhea
  - metastasis: lung, bone, brain, peritoneal seeding

Secondary liver metastases are common in many cancers, with some studies showing a prevalence of 40-50% amongst patients with extrahepatic cancers. They commonly arise from breast, lung, and colorectal cancers. For metastases secondary to colorectal cancer, surgical resection offers the greatest likelihood of cure.
Liver Transplantation

*Leading cause in adults; **Leading cause in children

Clinical Indications
- Year referral for transplant should be considered for all patients with progressive liver disease not responsive to medical therapy, especially:
  - Decompensated cirrhosis (ascites, esophageal variceal hemorrhage, spontaneous hepatic encephalopathy, coagulopathy, progressive jaundice, severe fatigue)
  - Unresectable primary liver cancers
  - Fulminant hepatic failure
  - End-stage liver disease with life expectancy <1 yr and if no other therapy is appropriate

Criteria for Transplantation
- Model for End-Stage Liver Disease (MELD): prognostic model to estimate 3 mo survival and disease severity if patient does not receive transplant; based on creatinine, bilirubin, INR; MELD scores from 6-40 used to prioritize liver allocation
- Child-Turcotte-Pugh Score: classification system to assess the prognosis and mortality of liver disease; patient must have ≥7 points (Class B)

Contraindications
- Active alcohol/substance abuse
- Extrahepatic malignancy within 5 yr
- Advanced cardiopulmonary disease
- Active uncontrolled infection
Post-Operative Complications
- primary non-function (graft failure): urgent re-transplantation is indicated
- acute and chronic rejection, ischemia-reperfusion injury
- vascular: hepatic artery or portal vein thrombosis, IVC obstruction
- biliary complications: fever, increasing bilirubin and ALP
- complications related to immunosuppression: HTN, renal disease, DM, obesity, hyperlipidemia, osteoporosis, malignancy, neurologic complications, infection (leading cause of mortality following transplant)

Prognosis
- patient survival at 1 yr: 85%
- graft survival at 1 yr: >80%, at 5 yr: 60-70%

Biliary Tract

Cholelithiasis

Definition
- the formation of gallstones

Pathogenesis
- imbalance of cholesterol and its solubilizing agents (bile salts and lecithin)
- excessive hepatic cholesterol secretion → bile salts and lecithin are “overloaded” → supersaturated cholesterol can precipitate and form gallstones
- North America: cholesterol stones (80%), pigment stones (20%)

Risk Factors
- cholesterol stones
  - obesity, age <50
  - estrogens: female, multiparity, OCPs
  - ethnicity: First Nations heritage (especially Pima Indians) > Caucasian > Black
  - terminal ileal resection or disease (e.g. Crohn’s disease)
  - impaired gallbladder emptying: starvation, TPN, DM
  - rapid weight loss: rapid cholesterol mobilization and biliary stasis
  - pigment stones (contain calcium bilirubinate)
  - cirrhosis
  - chronic hemolysis
  - biliary stasis (strictures, dilation, biliary infection)
  - protective factors: statins, vitamin C, coffee, exercise

Outcomes of Living and Deceased Donor Liver Transplant Recipients With Hepatocellular Carcinoma: Results of the A2ALL Cohort

Purpose: To compare the overall survival and hepatocellular carcinoma (HCC) recurrence rates after living donor liver transplantation (LDLT) vs. deceased donor liver transplantation (DDLT) in a series of patients with HCC.

Methods: Study conducted between 1998 and 2009 at nine clinical centers. 229 patients with HCC undergoing liver transplantation included, with approximately 57% transplanted prior to MELD score implementation.

Results: The 5 yr survival rates were 59% in LDLT recipients and 66% in DDLT recipients (HR=1.32; p=0.27). Recurrence-free survival between LDLT and DDLT recipients did not differ (without using MELD score HR=1.13; p=0.3). Using MELD score (HR=1.32, p=0.01), recurrence rates at 5 yr were lower in LDLT recipients (HR=2.33; p=0.04), but not significantly different than in DDLT recipients following introduction of MELD scoring (HR=1.36, p=0.57).

Conclusion: Overall survival was not significantly different between LDLT and DDLT recipients. Although the HCC recurrence rate was higher in LDLT recipients, it was most likely due to more advanced HCC prior to transplant and less liver-directed HCC therapy compared to DDLT.

Risk Factors for Cholesterol Stones
- 4F's
  - Fasting
  - Female
  - Fertile
  -Forties

Figure 27. Gallstone disease

Clinical Presentation
- asymptomatic (80%)
  - most do NOT require treatment
  - consider cholecystectomy if: increased risk of malignancy (choledochal cysts, Caroli’s disease, porcelain or calcified gallbladder), sickle cell disease, pediatric patient, bariatric surgery, immunosuppression
Clinical Features
- steady, severe dull pain in epigastrium or RUQ for minutes to hours, crescendo-decrescendo pattern
- may present with chest pain
- N/V
- frequently occurs at night or after fatty meal, not after fasting
- can radiate to right shoulder or scapula
- patients often restless
- no peritoneal findings, no systemic signs

Investigations
- normal blood work: CBC, electrolytes, LFTs, bilirubin, amylase
- U/S shows cholelithiasis, may show stone in cystic duct

Treatment
- analgesia, hydration during colic episode
- elective cholecystectomy (95% success)
- laparoscopic cholecystectomy, hospital stay, and morbidity during the waiting period for elective cholecystectomy for patients with uncomplicated biliary colic due to gallstones. Results: One trial with 75 participants, average age 43 yr. Early laparoscopic cholecystectomy (<24 h vs. delayed mean wait period 4.2 mo). The proportion of serious adverse events was lower in the early vs. delayed group (0% vs. 22.5%, respectively). There was a shorter hospital stay in the early group (MD -1.25 d, 95% CI -2.05 to -0.45) and a shorter operating time in the early group (MD -1.95 min, 95% CI -3.00 to -0.90). There was no difference in the proportion of patients requiring conversion to open cholecystectomy in the two groups. Conclusion: Early laparoscopic cholecystectomy (<24 h of diagnosis of biliary colic) decreased morbidity during the waiting period for elective laparoscopic cholecystectomy, hospital stay, and operating time.

Pathogenesis
- inflammation of gallbladder resulting from sustained gallstone impaction in cystic duct or Hartmann's pouch
- no cholelithiasis in 5-10% (see Acute Cholecystitis, GS47)

Clinical Features
- often have history of biliary colic
- severe constant (hours to days) epigastric or RUQ pain, anorexia, N/V, low grade fever (<38.5°C)

Acute Cholecystitis
Pathogenesis
- inflammation of gallbladder resulting from sustained gallstone impaction in cystic duct or Hartmann's pouch
- no cholelithiasis in 5-10% (see Acute Cholecystitis, GS47)
• focal peritoneal findings: Murphy’s sign, palpable, tender gallbladder (in 33%)
• Boas’ sign: right subscapular pain

**Investigation**
- blood work: elevated WBC and left shift, mildly elevated bilirubin, AST, ALT, and ALP
- U/S: 98% sensitive, consider HIDA scan if U/S negative

**Complications**
- gallbladder mucocele (hydrops): long-term cystic duct obstruction results in mucous accumulation in gallbladder (clear fluid)
- gangrene (20%), perforation (2%): result in abscess formation or peritonitis
- empyema of gallbladder: supplicative cholecystitis, pus in gallbladder + sick patient
- cholecystoenteric fistula, from repeated attacks of cholecystitis, can lead to gallstone ileus
- emphysematous cholecystitis: bacterial gas present in gallbladder lumen, wall, or pericholecystic space (risk in diabetic patient)
- organisms involved in secondary infection: *E. coli*, *Klebsiella*, *Enterococcus*
- Mirizzi syndrome: extra-luminal compression of CBD/CHD due to large stone in cystic duct

**Treatment**
- admit, hydrate, NPO, NGT (if persistent vomiting from associated ileus), analgesics once diagnosis is made
- antibiotics
  - cefazolin if uncomplicated cholecystitis
- cholecystectomy
  - early (within 72 h) vs. delayed (after 6 wk)
    - equal morbidity and mortality
    - early cholecystectomy preferred: shorter hospitalization and recovery time, no benefit to delaying surgery
    - emergent OR indicated if high risk, e.g. emphysematous
  - laparoscopic: reduced risk of wound infections, shorter hospital stay, reduced post-operative pain, increased risk of bile duct injury
- intraoperative cholangiography (IOC)
  - indications: clarify bile duct anatomy, obstructive jaundice, history of biliary pancreatitis, small stones in gallbladder with a wide cystic duct (>15 mm), single faceted stone in gallbladder, bilirubin >8 mg/dL.
  - percutaneous cholecystostomy tube: critically ill or if general anesthetic contraindicated

### Acalculous Cholecystitis

**Definition**
- acute or chronic cholecystitis in the absence of stones

**Pathogenesis**
- typically due to gallbladder ischemia, stasis

**Risk Factors**
- DM, immunosuppression, ICU admission, trauma patient, TPN, sepsis

**Clinical Features**
- see **Acute Cholecystitis**, GS46
- occurs in 20% of cases of acute cholecystitis

**Investigations**
- U/S: shows sludge in gallbladder, other U/S features of cholecystitis (see **Acute Cholecystitis**, GS46)
- CT or HIDA scan

**Treatment**
- broad-spectrum antibiotics, cholecystectomy
- if patient unstable → cholecystostomy

### Choledocholithiasis

**Definition**
- stones in CBD

**Clinical Features**
- 50% asymptomatic
- often have history of biliary colic
- tenderness in RUQ or epigastrium
- acholic stool, dark urine, fluctuating jaundice
• primary vs. secondary stones
  ▪ primary: formed in bile duct, indicates bile duct pathology (e.g. benign biliary stricture, sclerosing cholangitis, choledochal cyst, CF)
  ▪ secondary: formed in gallbladder (85% of cases in U.S.)

Investigations
• CBC: usually normal; leukocytosis suggests cholangitis
• LFTs: increased AST, ALT early in disease, increased bilirubin (more sensitive), ALP, GGT later
• amylase/lipase: to rule out gallstone pancreatitis
• U/S: intra-/extra-hepatic duct dilatation; differential diagnosis is choledochal cyst
• ERCP, PTC
• MRCP (90% sensitive, almost 100% specific, not therapeutic)

Complications
• cholangitis, pancreatitis, biliary stricture, and biliary cirrhosis

Treatment
• if no evidence of cholangitis: treat with ERCP for CBD stone extraction possibly followed by elective cholecystectomy in 25% of patients

Acute Cholangitis

Pathogenesis
• obstruction of CBD leading to biliary stasis, bacterial overgrowth, suppuration and biliary sepsis – may be life-threatening, especially in elderly

Etiology
• choledocholithiasis (60%), stricture, neoplasm (pancreatic or biliary), extrinsic compression (pancreatic pseudocyst or pancreatitis), instrumentation of bile ducts (PTC, ERCP), biliary stent
• organisms: *E. coli*, *Klebsiella*, *Pseudomonas*, *Enterococcus*, *B. fragilis*, *Proteus*

Clinical Features
• Charcot's triad: fever, RUQ pain, jaundice
• Reynold's pentad: fever, RUQ pain, jaundice, shock, confusion
• may have N/V, abdominal distention, ileus, acholic stools, tea-colored urine (elevated direct bilirubin)

Investigations
• CBC: elevated WBC + left shift
• may have positive blood cultures
• LFTs: obstructive picture (elevated ALP, GGT, and conjugated bilirubin, mild increase in AST, ALT)
• amylase/lipase: rule out pancreatitis
• U/S: intra-/extra-hepatic duct dilatation

Treatment
• initial: NPO, fluid and electrolyte resuscitation, ± NGT, IV antibiotics (treats 80%)
• biliary decompression
  ▪ ERCP + sphincterotomy: diagnostic and therapeutic
  ▪ PTC with catheter drainage: if ERCP not available or unsuccessful
  ▪ laparotomy with CBD exploration and T-tube placement if above fails
• all patients should also have a cholecystectomy, unless contraindicated

Prognosis
• suppurative cholangitis mortality rate: 50%

Gallstone Ileus

Pathogenesis
• repeated inflammation causing a cholecystoenteric fistula (usually duodenal) → large gallstone enters the gut and impacts at or near the ileocecal valve, causing a true bowel obstruction (note: ileus is a misnomer in this context)

Clinical Features
• crampy abdominal pain, N/V (see *Bowel Obstruction*, GS24)

Investigations
• AXR: dilated small intestine, air fluid levels, may reveal radiopaque gallstone, air in biliary tree (pneumobilia) (40%)
• CF: biliary tract air, obstruction, gallstone in intestine
• Rigler's triad: pneumobilia (air in biliary tree), small bowel obstruction (partial or complete), gallstone (usually in right iliac fossa)

Laparoscopic vs. Open Cholecystectomy
• Shorter operating time
• Shorter length of stay
• Shorter sick leave
• Shorter time to return to daily activities
• Less post-operative pain
• Decreased use of post-operative analgesia
• Decreased reduction in pulmonary function*
• Fewer pulmonary complications
• Decreased acute phase response
• Less impairment in intestinal motility*

Open Cholecystectomy
• Lower conversion rates to open surgery (for mini-laparotomies)

American Society of Gastrointestinal Endoscopy 2010 Predictors for Risk of CBD Stones
• Very strong:
  ▪ CBD stone on ultrasound
  ▪ Clinical ascending cholangitis
  ▪ Bilirubin >4 mg/dL
• Strong:
  ▪ CBD dilated >6 mm on ultrasound
  ▪ Bilirubin 1.8-4 mg/dL
• Moderate:
  ▪ Abnormal liver test (besides bilirubin)
  ▪ Age >55 yr
  ▪ Clinical gallstone pancreatitis

Charcot's Triad
Fever, RUQ pain, jaundice

Reynold's Pentad
Fever, RUQ pain, jaundice, shock, confusion

Rigler's Triad of Gallstone Ileus
• Pneumobilia
• Small bowel obstruction
• Gallstone

Pneumobilia
• *Enterobacter*
• *Proteus*, *Pseudomonas*
• *Serratia*

Common Bacteria in Biliary Tract
KEEPS
*Klebsiella*
*Enterococcus*
*E. coli*, *Enterobacter*
*Proteus*, *Pseudomonas*
*Serratia*
### Treatment
- Fluid resuscitation, NGT decompression
- Surgery: enterolithotomy and removal of stone, inspect small and large bowel for additional proximal stones
- May close fistula surgically or manage expectantly (can resolve spontaneously)
- Cholecystectomy either during enterolithotomy or after recovery if patient experiences gallbladder symptoms

### Carcinoma of the Gallbladder

#### Risk Factors
- Chronic symptomatic gallstones (70% of cases), old age, female, gallbladder polyps, porcelain gallbladder, chronic infection (*Salmonella, Helicobacter*), abnormal pancreaticobiliary duct junction

#### Clinical Features
- Majority are adenocarcinoma
- May be incidental finding on elective cholecystectomy (~1% of elective cholecystectomies)
- Many patients are asymptomatic until late
- Local: non-specific RUQ pain, palpable RUQ mass
- Courvoisier’s gallbladder: an enlarged, often palpable gallbladder in a patient with carcinoma of the head of the pancreas; associated with jaundice due to obstruction of the CBD
- Systemic: jaundice (50%) due to invasion of CBD or compression of CBD by pericholedochal nodes, weight loss, malaise, anorexia
- Early local extension to liver, may extend to stomach, duodenum
- Early metastasis common to liver, lung, bone

#### Investigations
- U/S: mural thickening, calcification, loss of interface between gallbladder and liver, fixed mass
- Endoscopic U/S (EUS): good for distinguishing carcinomas from other diagnoses such as polyps, good for staging, allows sampling of bile for cytology
- Abdominal CT: polypoid mass, mural thickening, liver invasion, nodal involvement, distant metastases
- MRI/MRCP: good for distinguishing benign and malignant polyps

#### Treatment
- If carcinoma of the gallbladder is suspected pre-operatively, an open cholecystectomy should be considered to avoid tumor seeding of the peritoneal cavity
- Confined to mucosa (rare): cholecystectomy
- Beyond mucosa: cholecystectomy, en bloc wedge resection of 3–5 cm underlying liver, dissection of hepatoduodenal lymph nodes

#### Prognosis
- Poor 5 yr survival (10%) as gallbladder carcinoma is often detected late
- Better outcomes when detected incidentally following cholecystectomy

### Cholangiocarcinoma

#### Definition
- Malignancy of extra- or intrahepatic bile ducts

#### Risk Factors
- Age 50–70, gallstones, ulcerative colitis, primary sclerosing cholangitis, choledochal cyst, *Clonorchis sinensis* infection (liver fluke), chronic intrahepatic stones (hepatolithiasis)

#### Clinical Features
- Majority are adenocarcinomas
- Gradual signs of biliary obstruction: jaundice, pruritus, dark urine, pale stools
- Anorexia, weight loss, RUQ pain, Courvoisier’s sign (if CBD obstructed), hepatomegaly
- Early metastases are uncommon, but commonly tumor grows into portal vein or hepatic artery
- Klatskin tumor: cholangiocarcinoma located at bifurcation of common hepatic duct

#### Investigations
- LFTs show obstructive picture
- U/S, CT: bile ducts usually dilated, but not necessarily
- ERCP or PTC: to determine resectability, for biopsies
- CXR, bone scan: for metastatic workup
Treatment
- if resectable: biliary drainage and wide excision margin
  - upper third lesions: duct resection + Roux-en-Y hepaticojejunostomy, ± liver resection
  - middle third lesions (uncommon): duct resection + Roux-en-Y hepaticojejunostomy
  - lower third lesions: Whipple procedure
- unresectable lesions: stent or choledochojejunostomy (surgical bypass)
- chemotherapy ± radiotherapy
- role for transplantation in some patients with Klatskins tumors

Prognosis
- radiotherapy useful for additional palliation, chemotherapy may be helpful
- the more proximal to the liver, the worse the prognosis
- overall 5 yr survival: 15%

Pancreas

Acute Pancreatitis

• see Gastroenterology, G45

GALLSTONE PANCREATITIS (35% of acute pancreatitis)

Pathogenesis
- obstruction of pancreatic duct by large or small gallstones and biliary sludge
- backup of pancreatic enzymes can cause autodigestion of the pancreas

Clinical Features (pancreatitis of any etiology)
- pain (epigastric pain radiating to back), N/V, ileus, peritoneal signs, jaundice, fever
- Inglefingar’s sign: pain worse when supine, better when sitting forward
- rarely may have existent cholangitis or pancreatic necrosis
- Ranson’s criteria for determining prognosis of acute pancreatitis (see sidebar)
- physical exam may show: tachypnea, tachycardia, hypotension, abdominal distention and tenderness, Cullen’s sign, Gray Turner’s sign

Investigations
- high amylase (higher than alcoholic pancreatitis), lipase, leukocytosis
- elevated ALT (>150 IU/L), AST strongly suggest gallstone etiology of pancreatitis
- U/S may show multiple stones (may have passed spontaneously), edematous pancreas
- CXR, AXR, CT (if severe to evaluate for complications)

Treatment
- supportive: e.g. NPO, hydration, analgesia, early enteric nutrition
- antibiotics for severe cases of necrotizing pancreatitis or signs of sepsis
- stone often passes spontaneously (~90%); usually no surgical management in uncomplicated acute pancreatitis
- cholecystectomy during same admission (25-60% recurrence if no surgery)
- may need urgent ERCP + sphincterotomy if failure of conservative management if stone impacted in CBD (benefits of early ERCP controversial)
- early ERCP if concomitant cholangitis
- surgical indications in acute pancreatitis (rare)
  - debridement and drain placement for necrotizing pancreatitis if refractory to medical management, if septic or in ICU without other sources of sepsis

Complications
- pseudocyst (collection of pancreatic secretions >4 wk old surrounded by a defined wall of granulation tissue)
- abscess/infection, necrosis
- splenic/mesenteric/portal vessel thrombosis or rupture
- pancreatic ascites/pancreatic pleural effusion
- DM
- ARDS/sepsis/multiorgan failure
- coagulopathy/DIC
- encephalopathy
- severe hypocalcemia
Chronic Pancreatitis

• see Gastroenterology, G47

Surgical Treatment
• treatment is generally medical
• indications for surgery
  • failure of medical treatment
  • debilitating abdominal pain
  • pseudocyst complications: persistence, hemorrhage, infection, rupture
  • CBD obstruction (e.g. strictures), duodenal obstruction
  • pancreatic fistula, variceal hemorrhage secondary to splenic vein obstruction
  • rule out pancreatic cancer (present in 15% of chronic pancreatitis treated surgically)
  • anatomical abnormality causing recurrent pancreatitis
• pre-operative CT and/or ERCP are mandatory to delineate anatomy
• minimally invasive options
  • endoscopic pancreatic duct decompression: less effective than surgery
  • extracorporeal shockwave lithotripsy: if pancreatic duct stones
  • celiac plexus block: lasting benefit in 30% patients, less effective in those <45 yr or with prior pancreatic surgery
• surgical options
  • drainage procedures: only effective if ductal system is dilated
    • Puestow procedure (lateral pancreaticojejunostomy): improves pain in 80% of patients
    • pancreaticojejunostomy: best option in absence of dilated duct
  • proximal disease: Whipple procedure (pancreatoduodenectomy) – pain relief in 80%
  • distal disease: distal pancreatectomy ± Roux-en-Y pancreaticojejunostomy
  • total pancreatectomy: refractory disease
  • denervation of celiac ganglion and splanchnic nerves

PSEUDOCYST
• localized fluid collections rich in pancreatic enzymes, with a non-epithelialized wall consisting of fibrous and granulation tissue
• complication of chronic and/or acute pancreatitis
• often resolve spontaneously
• cyst wall must be mature prior to drainage (4-6 wk)
• pseudoaneurysm an absolute contraindication to endoscopic drainage, must embolize first

Treatment
• surgical drainage (gold standard)
  • cystgastrostomy
  • cystenterostomy
  • resection
• endoscopic drainage
  • cystgastrostomy
  • cystduodenostomy
  • percutaneous catheter drainage
• consider biopsy of cyst wall to rule out cystadenocarcinoma

Pancreatic Cancer

Epidemiology
• fourth most common cause of cancer-related mortality in both men and women in Canada
• M:F = 1.3:1, average age: 50-70

Risk Factors
• increased age
• smoking: 2-5x increased risk, most clearly established risk factor
• high fat/low fiber diets, heavy alcohol use
• obesity
• DM, chronic pancreatitis
• partial gastrectomy, cholecystectomy
• chemicals: betanaphthylamine, benzidine
• African descent

Clinical Features
• head of the pancreas (70%)
  • weight loss, obstructive jaundice, steatorrhea, vague constant mid-epigastric pain (often worse at night, may radiate to back)
  • painless jaundice (occurs more often with peri-ampullary), Courvoisier’s sign (see sidebar GS49)
• body or tail of pancreas (30%)
  • tends to present later and usually inoperable
  • weight loss, vague mid-epigastric pain
  • <10% jaundiced
  • sudden onset DM
Investigations
- serum chemistry is non-specific, can have elevated ALP and bilirubin >300 µmol/L
- CA 19-9 (most useful serum marker of pancreatic cancer)
- U/S, contrast CT (also evaluates metastasis and resectability), ERCP, MRI, MRCP

Pathology
- ductal adenocarcinoma: most common type (75-80%); exocrine pancreas
- intraductal papillary mucinous neoplasm (IPMN)
- other: pancreatic neuroendocrine tumors (non-functional, insulinoma, gastrinoma, VIPoma, glucagonoma, somatostatinoma), mucinous cystic neoplasm (MCN), acinar cell carcinoma,
  - see Surgical Endocrinology, GS60 for functional pancreatic neuroendocrine tumors

Treatment
- resectable (10-20% of pancreatic cancer)
  - no involvement of liver, peritoneum, or vasculature (hepatic artery, SMA, SMV, portal vein, IVC, aorta), no distant metastasis
  - Whipple procedure (pancreaticoduodenectomy) for cure <5% mortality
  - distal pancreatectomy ± splenectomy, lymphadenectomy if carcinoma of midbody and tail of pancreas
- borderline resectable
  - tumors that abut the SMA, SMV, portal vein, hepatic artery, or celiac artery
  - non-resectable (palliative ± relieve pain, obstruction)
  - most body/tail tumors are not resectable (due to late presentation)
  - relieve biliary/duodenal obstruction with endoscopic stenting or double bypass procedure (choledochoenterostomy + gastroenterostomy)
  - chemotherapy (gemcitabine, 5-FU), radiotherapy – only slightly increase survival

Prognosis
- most important prognostic indicators are lymph node status, margin status, size >3 cm, perineural invasion (invasion of tumor into microscopic nerves of pancreas)
- overall 5 yr survival for all patients with pancreas cancer is 1%; following surgical resection 5 yr survival is 20%
- median survival for unresectable disease: 3-6 mo if metastatic, 8-12 mo if locally advanced at presentation

Spleen

Splenic Trauma

- typically from blunt trauma (especially in people with splenomegaly)
- most common intra-abdominal organ injury in blunt trauma
- may have Kehr’s sign

Treatment

- non-operative
  - in stable patients: extended bed rest with serial hematocrit levels, close monitoring for 3-5 d; pediatric guidelines for days of bed rest is grade plus 1 (i.e. grade 3 splenic laceration requires 4 d of bed rest)
  - hemostatic control
  - splenic artery embolization if patient stable and one of: active contrast extravasation, splenic pseudoaneurysm, hemoperitoneum
- operative
  - splenorrhaphy (suture of spleen) ± splenic wrapping with hemostatic mesh – if patient hemodynamically stable, patient has stopped bleeding and laceration does not involve hilum
  - partial splenectomy, rarely performed due to risk of recurrent hemorrhage
  - total splenectomy if patient unstable or high-grade injury

Splenectomy

Indications

- splenic trauma (most common reason for splenectomy), hereditary spherocytosis, primary hypersplenism, chronic immune thrombocytopenic purpura (ITP), splenic vein thrombosis causing esophageal varices, splenic abscess, thrombotic thrombocytopenic purpura (TTP), sickle cell disease
- does not benefit all thrombocytopenic states (e.g. infection, most malignancies involving the bone marrow, drugs/toxins)
- probability of cure of ITP by splenectomy is 60-70%, may be predicted by response to IVIg

Complications

- short-term
  - injury to surrounding structures (e.g. gastric wall, tail of pancreas)
  - post-operative thrombocytosis, leukocytosis
  - thrombosis of portal, splenic, or mesenteric veins
  - subphrenic abscess
- long-term
  - post-splenectomy sepsis (encapsulated organisms): 4% of splenectomized patients (highest risk in those <16 yr old)
    - 50% mortality
    - prophylaxis with vaccinations, ideally 2 wk pre- or post-operative (pneumococcal, H. influenzae, and meningococcus)
    - liberal use of penicillin especially in children <6 yr old
    - splenosis: intra-abdominal “seeding” of splenic tissue during removal

Kehr’s Sign
Left shoulder pain due to diaphragmatic irritation from splenic rupture, worsens with inspiration

Indication of Splenectomy

SHIRTS
Splen ic abscess/splenomegaly
Hereditary spherocytosis
Immune thrombocytopenic purpura
Rupture of spleen
Thrombotic thrombocytopenic purpura
Splenic vein thrombosis
**Benign Breast Lesions**

**NON-PROLIFERATIVE LESIONS**
- also known as fibrocystic change, chronic cystic mastitis, mammary dysplasia
- benign breast condition characterized by fibrous and cystic changes in the breast
- no increased risk of breast cancer
- age 30 to menopause (and after if HRT used)
  - clinical features
  - breast pain, focal areas of nodularity or cysts often in the upper outer quadrant, frequently bilateral, mobile, varies with menstrual cycle, nipple discharge (straw-like, brown, or green)
- treatment
  - evaluation of breast mass and reassurance
  - if >40 yr old: mammography every 3 yr
  - no strong evidence for avoidance of xanthine-containing products (coffee, tea, chocolate, cola)
  - analgesia (ibuprofen, ASA)
  - for severe symptoms: OCP, danazol, bromocriptine

**PROLIFERATIVE LESIONS – No Atypia**

**Fibroadenoma**
- most common benign breast tumor in women <30 yr
- risk of subsequent breast cancer is increased only if fibroadenoma is complex, there is adjacent atypia, or a strong family history of breast cancer
- clinical features
  - nodules: smooth, rubbery, discrete, well-circumscribed, non-tender, mobile, hormone-dependent
  - unlike cysts, needle aspiration yields no fluid
- investigations
  - core or excisional biopsy required
  - U/S and FNA alone cannot differentiate fibroadenoma from Phyllodes tumor
- treatment
  - generally conservative: serial observation
  - consider excision if size 2-3 cm and growing on serial U/S (q6mo x 2 yr is usual follow-up), if symptomatic, formed after age 35, or patient preference

**Intraductal Papilloma**
- solitary intraductal benign polyp
- present as nipple discharge (most common cause of spontaneous, unilateral, bloody nipple discharge), breast mass, nodule on U/S
- can harbor areas of atypia or DCIS
- treatment: excision of involved duct to ensure no atypia

**DDx for Breast Mass**

**Benign**
- Fibrocystic changes
- Fibroepithelial lesions (fibroadenoma most common; benign phyllodes also)
- Fat necrosis
- Papilloma/papillomatosis
- Galactoceles
- Duct ectasia
- Ductal/lobular hyperplasia
- Sclerosing adenosis
- Lipoma
- Neurofibroma
- Granulomatous mastitis (e.g. TB, granulomatosis with polyangiitis, sarcoidosis)
- Abscess
- Silicone implant

**Malignant**
- Breast cancer (likely invasive, DCIS rarely forms a breast mass)
- Malignant phyllodes
- Angiosarcoma (rare)
Ductal Hyperplasia Without Atypia
• increased number of cells within the ductal space
• cells retain benign cytology
• no treatment required
• slightly increased cancer risk if moderate or florid hyperplasia

PROLIFERATIVE LESIONS – With Atypia

Atypical Hyperplasias
• can involve ducts (ductal hyperplasia with atypia) or lobules (lobular hyperplasia with atypia)
• cells lose apical-basal orientation
• increased risk of breast cancer
• diagnosis: core or excisional biopsy
• treatment: complete resection, risk modification (avoid exogenous hormones), close follow-up

OTHER LESIONS

Fat Necrosis
• uncommon, result of trauma (may be minor, positive history in only 50%), after breast surgery (i.e. reduction)
• firm, ill-defined mass with skin or nipple retraction, ± tenderness
• regresses spontaneously, but complete imaging ± biopsy to rule out carcinoma

Mammary Duct Ectasia
• obstruction of a subareolar duct leading to duct dilation, inflammation, and fibrosis
• may present with nipple discharge, bluish mass under nipple, local pain
• risk of secondary infection (abscess, mastitis)
• resolves spontaneously

Montgomery Tubercle
• Montgomery tubercles (or Morgagni tubercles) are papular projections at the edge of the areola
• obstruction of these glands can lead to inflammation or cystic collections (cyst of Montgomery i.e. retroareolar cyst)
• if signs of secondary infection, start treatment for mastitis
• resolves spontaneously in weeks to years

Abscess
• lactational (see Obstetrics, OB49) vs. periductal/subareolar
• unilateral localized pain, tenderness, erythema, subareolar mass, nipple discharge, nipple inversion
• rule out inflammatory carcinoma, as indicated
• treatment: initially broad-spectrum antibiotics and I&D, if persistent total duct excision (definitive)
• if mass does not resolve: U/S to assess for presence of abscess, core biopsy to exclude cancer, consider MRI

Breast Cancer

Epidemiology
• 2nd leading cause of cancer mortality in women (1st is lung cancer)

Risk Factors
• gender (99% female)
• age (80% >40 yr)
• important risk factors are prior history of breast cancer and/or prior breast biopsy (regardless of pathology)
• 1st degree relative with breast cancer (greater risk if relative was premenopausal)
• increased risk with high breast density, nulliparity, first pregnancy >30 yr, menarche <12 yr, menopause >55 yr
• decreased risk with lactation, early menopause, early childbirth
• radiation exposure (e.g. mantle radiation for Hodgkin’s disease)
• >5 yr HRT
Investigations
- mammography
  - indication
    - screening, see Family Medicine, FM4
    - findings indicative of malignancy
      - mass that is poorly defined, spiculated border
      - microcalcifications
      - architectural distortion
      - interval mammographic changes
      - normal mammogram does not rule out suspicion of cancer based on clinical findings
  - other radiographic studies
    - U/S: differentiate between cystic and solid
    - MRI: high sensitivity, low specificity
    - galactogram/ductogram (for nipple discharge): identifies lesions in ducts
    - metastatic workup as indicated (usually after surgery or if clinical suspicion of metastatic disease): bone scan, abdominal U/S, CXR (or CT chest/abdomen/pelvis), CT head (only if specific neurological symptoms)

Diagnostic Procedures
- needle aspiration: for palpable cystic lesions; send fluid for cytology if blood or cyst does not completely resolve
- U/S or mammography guided core needle biopsy (most common)
- fine needle aspiration (FNA): for palpable solid masses; need experienced practitioner for adequate sampling
- excisional biopsy: only performed as second choice to core needle biopsy; should not be done for diagnosis if possible

Genetic Screening
- consider testing for BRCA1/2 if:
  - patient diagnosed with breast AND ovarian cancer
  - strong family history of breast/ovarian cancer
  - family history of male breast cancer
  - young patient (<35 yr)
  - bilateral breast cancer in patients <50 yr

Staging
- clinical
  - tumor size by palpation, mammogram
  - nodal involvement by palpation
  - metastasis by physical exam, CXR, and abdominal U/S (or CT chest/abdomen/pelvis), bone scan (usually done post-operative if node-positive disease)
- pathological
  - tumor size
    - grade: modified Bloom and Richardson score (I to III) – histologic, nuclear, and mitotic grade
    - number of axillary nodes positive for malignancy out of total nodes resected, extranodal extension, sentinel node positive/negative
    - estrogen receptor (ER) + progesterone receptor (PR) testing
    - Her2Neu receptor testing
    - margins: negative, <1 mm, positive
    - lymphovascular invasion (LVI)
    - extensive in situ component (EIC): DCIS in surrounding tissue
    - involvement of dermal lymphatics (inflammatory) – automatically Stage IIIb

</table>

Favorable Features
- <2 cm
- Grade I (low grade)
- Node negative
- ER positive
- Mucinous pattern

Unfavorable Features
- >5 cm
- Grade III (high grade)
- Node positive
- ER negative
- Inflammatory cancer
- Her2Neu positive
- Positive margins
- UV
- EIC
- Dermal lymphatics involved

Phyllodes tumors are rare fibroepithelial breast tumors that can be benign or malignant that mostly affect women from 35-55 yr

Any palpable dominant breast mass requires further investigation

Diagnostic mammography is indicated in all patients, even in women <50 yr
Pathology

- non-invasive (cannot penetrate basement membrane)
  - ductal carcinoma in situ (DCIS)
    - proliferation of malignant ductal epithelial cells completely contained within breast ducts, often multifocal
    - 80% non-palpable, detected by screening mammogram
    - risk of invasive ductal carcinoma in same breast up to 35% in 10 yr
  - treatment
    - lumpectomy with wide excision margins + radiation (5-10% risk invasive cancer)
    - mastectomy if large area of disease, high grade, or multifocal (risk of invasive cancer reduced to 1%)
    - possibly tamoxifen as an adjuvant treatment
    - 99% 5 yr survival
- lobular carcinoma in situ (LCIS)
  - neoplastic cells completely contained within breast lobule
  - no palpable mass, no mammographic findings, usually incidental finding on breast biopsy for another indication
  - treatment
    - clinical follow-up
    - chemoprevention (tamoxifen)
    - surgery (uncommon)
  - not a precursor lesion, but considered a risk factor for breast cancer development
- invasive
  - invasive ductal carcinoma (most common 80%)
    - originates from ductal epithelium and infiltrates supporting stroma
    - characteristics: hard, scirrhus, infiltrating tentacles, gritty on cross-section
  - invasive lobular carcinoma (8-15%)
    - originates from lobular epithelium
    - 20% bilateral (i.e. more often than infiltrating duct carcinoma)
    - does not form microcalcifications, harder to detect mammographically (may benefit from MRI)
  - Paget’s disease (1-3%)
    - ductal carcinoma that invades nipple with scaling, eczematoid lesion
  - inflammatory carcinoma (1-4%)
    - ductal carcinoma that invades dermal lymphatics
    - most aggressive form of breast cancer
    - clinical features: erythema, skin edema, warm, swollen and tender breast ± lump
    - peau d’orange indicates advanced disease (IIIb-IV)
  - male breast cancer (<1%)
    - most commonly invasive ductal carcinoma
    - often diagnosed at later stages
    - stage-for-stage similar prognosis to breast cancer in females
    - consider genetic testing
  - sarcomas: rare
    - most commonly Phyllodes tumor, a variant of fibroadenoma with potential for malignancy
    - can also be angiosarcomas – after previous radiation
  - lymphoma: rare
  - other: papillary, medullary, mucinous, tubular cancers
  - generally better prognosis

Treatment

Table 23. Breast Cancer Treatment by Stage

<table>
<thead>
<tr>
<th>Stage</th>
<th>Primary Treatment Options</th>
<th>Adjuvant Systemic Therapy</th>
</tr>
</thead>
</table>
| 0 (in situ) | BCS + radiotherapy  
BCS alone if margins > 1 cm and low nuclear grade  
Mastectomy* ± SLNB       | None                                      |
| I       | BCS + axillary node dissection + radiotherapy  
Mastectomy* ± axillary node dissection/SLNB       | May not be needed; discuss risks/benefits of chemotherapy and tamoxifen |
| II      | BCS + axillary node dissection + radiotherapy  
Mastectomy* ± axillary node dissection/SLNB       | Chemotherapy for premenopausal women or postmenopausal and estrogen receptor (ER) negative, followed by tamoxifen if ER positive |
| III     | Likely mastectomy + axillary node dissection + radiotherapy       | Neoadjuvant therapy may be considered i.e. pre-operative chemotherapy and/or hormone therapy. Adjuvant radiation and chemotherapy may also be appropriate (i.e. post-operative) |
| Inflammatory | Likely mastectomy + axillary node dissection + radiotherapy       | Neoadjuvant therapy                      |
| IV      | Surgery as appropriate for local control   | Primary treatment is systemic therapy i.e. chemotherapy and/or hormone therapy |

BCS = breast-conserving surgery; SLNB = sentinel lymph node biopsy

*If no reason to select mastectomy, the choice between BCS + radiotherapy and mastectomy can be made according to patient’s preference since choice of local treatment does not significantly affect survival if local control is achieved
Primary Surgical Treatment

- **BCS:** lumpectomy with wide local excision
  - for treatment of stage I and II disease
  - must be combined with radiation for survival equivalent to mastectomy
- **contraindications**
  - high risk of local recurrence: extensive malignant-type calcifications on mammogram, multifocal primary tumors, or failure to obtain tumor-free margins after re-excision
  - contraindications to radiation therapy (pregnancy, previous radiation, collagen vascular disease)
  - large tumor size relative to breast
- **mastectomy**
  - radical mastectomy (rarely done anymore): removes all breast tissue, skin, pectoralis muscle, axillary nodes
  - modified radical mastectomy (MRM): removes all breast tissue, skin, and axillary nodes
  - simple mastectomy: removes all breast tissue and skin
  - see Plastic Surgery, PL32 for breast reconstruction
- **axillary lymph node dissection (ALND)**
  - performed if SLNB is positive or nodes are clinically concerning
  - risk of arm lymphedema (10-15%), decreased arm sensation, shoulder pain
- **sentinel lymph node biopsy (SLNB)**
  - technetium-99 ± blue dye injected at tumor site prior to surgery to identify sentinel node(s)
  - intraoperative frozen section
  - proceed with ALND if positive
  - 5% false negative rate

Adjuvant/Neoadjuvant

- **radiation**
  - indications
    - decrease risk of local recurrence; almost always used after BCS, sometimes after mastectomy (if >4 nodes positive or tumor >5 cm)
    - inoperable locally advanced cancer
  - axillary nodal radiation may be added if nodal involvement
- **hormonal**
  - indications
    - ER positive plus node-positive or high-risk node-negative
    - tamoxifen if premenopausal or aromatase inhibitors (e.g. anastrozole)
    - ovarian ablation (e.g. goserelin/GnRH agonist, oophorectomy), progestins (e.g. megestrol acetate), androgens (e.g. fluoxymesterone) are other options
- **chemotherapy**
  - indications
    - ER negative plus node-positive or high-risk node-negative
    - stage I disease at high risk of recurrence (high grade, lymphovascular invasion)
    - palliation for metastatic disease

Post-Treatment Follow-Up

- visits q3-6mo x 2 yr and annually thereafter (frequency is controversial)
- annual mammography; no other imaging unless clinically indicated
- psychosocial support and counseling

Local/Regional Recurrence

- recurrence in treated breast or ipsilateral axilla
- 1% per year up to maximum of 15% risk of developing contralateral malignancy
- 5x increased risk of developing metastases

Metastasis

- bone > lungs > pleura > liver > brain
- treatment is palliative: hormone therapy, chemotherapy, radiation
Surgical Endocrinology

Thyroid and Parathyroid

• see Endocrinology, E20 and Otolaryngology, OT35-OT38

Thyroidectomy

• indications: thyroid cancer, symptomatic thyroid mass or goiter, medically refractory Graves' or hyperthyroidism
• contraindications: uncontrolled severe hyperthyroidism (i.e. Graves') due to risk of intraoperative or post-operative thyroid storm
• pre-operative workup: thyroid U/S for thyroid nodules, FNA for large nodules, U/S of the neck for lesions suspicious for papillary or medullary thyroid cancer, CT neck useful to rule out extension, vocal cord function
• complications: hypocalcemia secondary to hypoparathyroidism, recurrent/superior laryngeal nerve injury, neck hematoma, infection, thyrotoxic storm

Parathyroidectomy

• indications: symptomatic primary hyperparathyroidism due to effects of PTH on bone or kidneys, asymptomatic primary hyperparathyroidism with specific laboratory criteria (elevated serum Ca, marked hypercalciuria, Cr clearance <30% normal, bone density reduction with T score <2.5, age <50 yr)
• contraindications: familial hypocalciuric hypercalcemia
• pre-operative workup: 99mTc sestamibi scanning, ± SPECT or CT, U/S
• complications: recurrent/superior laryngeal nerve injury, post-operative hypocalcemia, infection, bleeding

Adrenal Gland

• see Endocrinology, E29
• functional anatomy
  ▪ cortex: glomerulosa (mineralocorticoids), fasciculata (glucocorticoids), reticularis (sex steroids)
  ▪ medulla: catecholamines (epinephrine, norepinephrine)
• types of adrenal tumors: functional (e.g. Cushing's syndrome, Conn's syndrome) or non-functional

INCIDENTALOMA

• adrenal mass discovered by investigation of unrelated symptoms

Epidemiology

• benign adenoma (38%) > metastases to adrenal (22%) >> cyst, carcinoma, pheochromocytoma, neuroblastoma
• metastasis to adrenal gland from: lung > breast, colon, lymphoma, melanoma, kidney
• peak incidence of carcinoma: females age 50-60, risk decreases with increasing age and male gender

Investigations

• MRI, CT: size >6 cm is best predictor of primary adrenal carcinoma (92% are >6 cm)
• functional studies
  ▪ pheochromocytoma: 24 h urine epinephrine, norepinephrine, metanephrine, normetanephrine, VMA (vanillylmandelic acid)
  ▪ Cushing's: 24 h urine cortisol or 1 mg overnight dexamethasone suppression test
  ▪ aldosteronoma: electrolytes, aldosterone:renin level, saline suppression test if appropriate
  ▪ adrenal androgens: 17-ÖH progesterone, DHEAS
• FNA biopsy: if suspect metastasis to adrenal (must exclude pheochromocytoma first to prevent a hypertensive crisis)
• indicated if history of cancer or patient is smoker
• iodocholesterol scintigraphy: may distinguish benign vs. malignant disease

Treatment

• functional tumor: resect
• non-functional tumor
  ▪ >4 cm: resect
  ▪ <4 cm: follow-up imaging in 6-12 mo, resect if >1 cm enlargement
INSULINOMA
• tumor that secretes insulin
• most common pancreatic endocrine neoplasm; 10% associated with MEN1 syndrome

Clinical Features
• Whipple's triad
  • palpitations, trembling, diaphoresis, confusion, seizure, personality changes

Investigations
• blood work: decreased serum glucose and increased serum insulin and C-peptide
• U/S, CT: insulinomas evenly distributed throughout head, body, tail of pancreas

Treatment
• only 10% are malignant
• enucleation of solitary insulinomas may be done endoscopically
• tumors >2 cm located close to the pancreatic duct may require pancreatectomy or pancreaticoduodenectomy

GASTRINOMA
• tumor secreting gastrin; cause of Zollinger-Ellison syndrome

Clinical Features
• abdominal pain, PUD, severe esophagitis
• multiple ulcers in atypical locations refractory of antacid therapy

Investigations
• blood work: serum gastrin levels (usually >1,000 pg/mL), secretin stimulation test
• U/S, CT: 70-90% found in Passaro's triangle (head of pancreas medially, 2nd portion of duodenum inferiorly, and the confluence of the cystic and CBD superiorly)
• octreotide scintigraphy scan

Treatment
• 50% are malignant
• surgical resection of tumor dependent on location
• non-surgical treatment: chemotherapy, somatostatin analogues, interferon, chemoembolization
• if inoperable, vagotomy can be performed for symptomatic control

VASOACTIVE INTESTINAL PEPTIDE-SECRETING TUMOR
• tumor secreting VIP; commonly located in the distal pancreas and most are malignant when diagnosed

Clinical Features
• severe watery diarrhea causing dehydration, weakness, electrolyte imbalance

Investigations
• blood work: serum VIP levels
• U/S, CT

Treatment
• somatostatin analogues
• surgical resection/palliative debulking

<tr>
<td><strong>Hydrocele (see Urology, U28)</strong></td>
<td>1-2% of live births  Present at birth, majority close spontaneously by 1 yr  M:F = 6:1  Prematurity</td>
<td><strong>Communicating hydroceles</strong>: processus vaginalis fails to close with small opening for fluid to move freely between peritoneal cavity through patent processus (if opening progresses to allow passage of intestine, it is a hernia)</td>
<td>Painless scrotal mass  Communicating hydroceles increase in size with standing or Valsalva, may be absent in the morning and large in the evening</td>
<td>Transillumination suggests hydrocele  Silk glove sign: gently palpating hydrocele sac over pubic tubercle feels like rubbing silk on silk</td>
<td>U/S if suspect pathology</td>
<td>Most resolve spontaneously by 1 yr  Surgical repair if:  – Persistence &gt;2 yr  – Pain  – Fluctuating in size which suggests communication  – Cosmetic reasons  – Infection</td>
<td>&lt;2% recurrence</td>
</tr>
<tr>
<td><strong>Hypertrophic Pyloric Stenosis</strong></td>
<td>0.03-1.0% of live births  Can present at 1-20 wk, most commonly at 6-8 wk  M:F = 4:1  Early erythromycin exposure (&lt;13 d old)</td>
<td>Acquired pyloric circular muscle hypertrophy results in gastric outlet obstruction  Hypovolemia caused by emesis of gastric contents causes hyperchloremic metabolic alkalosis  Electrolyte exchange based volume retention in kidneys results in paradoxical aciduria</td>
<td>Projectile non-bilious vomiting  Vomiting 30-60 min after feeds  Hangry after vomiting  Dehydration (variable severity)</td>
<td>Smooth oblong 1-2 cm mass palpable above umbilicus, “olive”  Visible left-to-right gastric contraction “waves” after feeding</td>
<td>Electrolytes (assess hypochloremia, dehydration)  U/S shows pyloric length &gt;14 mm, muscle thickness &gt;4 mm  Upper GI series necessary only when U/S unavailable or non-diagnostic will show “string sign”</td>
<td>Fluid reuscitate with normal saline, correct electrolyte and acid-base abnormalities with D5, 1/2NS + 20 mEq/L KCl at maintenance rate  NGT decompression unnecessary  Pyloromyotomy, open (Flamstedt vs. transumbilical or laparoscopic approach)  Alternative therapies such as TPN/wat or atroine impractical due to long time course of effect</td>
<td>Pyloromyotomy curative</td>
</tr>
<tr>
<td><strong>Congenital Diaphragmatic Hernias</strong></td>
<td>1 in 2,000 to 5,000 live births  Presents within hours of life although some cases of delayed presentation  M:F = 10% are associated with other congenital anomalies  Prenatal diagnosis common</td>
<td><strong>Left-sided</strong>: small bowel, large bowel, stomach, and solid visera (spleen, left lobe of liver) herniate into thorax  <strong>Right-sided</strong>: liver, large bowel herniate into thorax  Pulmonary hypoplasia  Pulmonary HTN  Early respiratory distress  Cyanosis  Scaphoid abdomen  Prenatal diagnosis  Decreased air entry ± bowel sounds in the chest  Displaced heart sounds  Echocardiography  Genetic consultation if warranted</td>
<td>Intubate  Orogastric suction  Period of respiratory stabilization due to associated pulmonary hypoplasia (may require extracorporeal membrane oxygenation)  Surgical repair after stable by hernia reduction and closure of diaphragmatic defect – open vs. thoracoscopic vs. laparoscopic with or without prosthetic or muscular patch depending on size of defect  Later presentations have better outcomes  Hearing deficit (40%)  Associated Gerd  MSK defects – chest wall and scoliotic defects a potential complication of thoracotomy</td>
<td>Later presentations have better outcomes  Hearing deficit (40%)  Associated Gerd  MSK defects – chest wall and scoliotic defects a potential complication of thoracotomy</td>
<td>Later presentations have better outcomes  Hearing deficit (40%)  Associated Gerd  MSK defects – chest wall and scoliotic defects a potential complication of thoracotomy</td>
<td>Need for long-term surveillance for potential recurrence  Failure to thrive  Chronic lung disease if severe hypoplasia</td>
<td></td>
</tr>

<tbody>
<tr>
<td><strong>Meckel’s Diverticulum</strong>&lt;br&gt;Most common remnant of vitelline duct that connects yolk sac with primitive midgut</td>
<td>1:3% of population&lt;br&gt;M/F = 2:1&lt;br&gt;Present most frequently during first 5 yr of life&lt;br&gt;Symptomatic in 2% of cases</td>
<td>Failure of vitelline duct to regress 5-7 wk in utero; 30% contain heterotopic tissue (e.g. gastric mucosa, ectopic pancreas); other associated anomalies include omphaloemiserentric fistula, umbilical sinus, umbilical cyst, fibrous band</td>
<td>BRBPR (heterotopic gastric mucosa in Meckel’s causing mucosal ulceration and bleeding in adjacent small bowel mucosa)&lt;br&gt;Abdominal sepsis (Meckel’s diverticulitis ± perforation)&lt;br&gt;Small bowel volvulus around fibrous band</td>
<td>Tenderness (lower abdomen) near umbilicus</td>
<td>AXR: Meckel scan; scan for ectopic gastric mucosa with technetium Tc99m pertechnetate IV (sensitivity 85%, specificity 95%)</td>
<td>Stabilize, resection by laparotomy or laparoscopy ± incidental appendectomy</td>
<td>Resection curative</td>
</tr>
<tr>
<td><strong>Malrotation</strong>&lt;br&gt;1:500 live births&lt;br&gt;1/3 present by 1 wk of age, 3/4 by 1 mo of age, 90% by 1 yr of age&lt;br&gt;M:F = 1:1; higher incidence among patients with cardiac anomalies, heterotaxy syndromes</td>
<td>Failure of gut to normally rotate around SMA with associated abnormal intestinal attachments and anatomic positions&lt;br&gt;Represent a spectrum of rotational abnormalities including complete non-rotation (which is not at high risk for volvulus)</td>
<td>Bilious emesis is THE cardinal sign, especially if abdomen nondistended&lt;br&gt;If bilious emesis in ill child with distended abdomen, consider surgical exploration to rule out volvulus&lt;br&gt;Rectal bleed (late/ ominous sign) Intermittent symptoms</td>
<td>Bilious drainage from NGT&lt;br&gt;Tachycardic, pale&lt;br&gt;Diaphoretic&lt;br&gt;Flat abdomen</td>
<td>AXR: obstruction of proximal small bowel, double-bubble sign, intestinal wall thickened&lt;br&gt;Immediate UGI: dilated duodenum, duodenojejunal segment (Ligament of Treitz) right of midline and not fixed posteriorly over spinal column, “corkscrew” sign indicating volvulus&lt;br&gt;U/S: “whirlpool” sign, abnormal SMA/SMV relationship indicates UGI to rule out rotational anomalies</td>
<td>IV antibiotics&lt;br&gt;Fluid resuscitation&lt;br&gt;EMERGENT LAPAROTOMY&lt;br&gt;Ladd procedure: counterclockwise reduction of midgut volvulus, division of Ladd’s bands, division of peritoneal attachments between cecum and abdominal wall that obstruct duodenum, broadening of the mesentery (open folded mesentery like a book and divide congenital adhesions), ± appendectomy&lt;br&gt;Positioning the bowel into non-rotation (small bowel in right abdomen, large bowel in left abdomen)</td>
<td>Mortality related to length of bowel loss: 10% necrosis – 100% survival rate, 75% necrosis – 35% survival rate&lt;br&gt;Recurrence 2-6%</td>
<td></td>
</tr>
<tr>
<td><strong>Gastrochisis</strong>&lt;br&gt;1:2,000 live births&lt;br&gt;Antenatal diagnosis common&lt;br&gt;Increased with younger maternal age and associated with EUR&lt;br&gt;M/F = 1:1</td>
<td>Defect of abdominal wall, with free extrusion of intestine into amniotic cavity&lt;br&gt;No specific environmental factor identified&lt;br&gt;Defect in embryogenesis unclear</td>
<td>Not associated with genetic syndromes&lt;br&gt;10% with intestinal atresia&lt;br&gt;Some cases associated with short bowel syndrome due to antenatal volvulus and necrosis of hemirotated bowel</td>
<td>Hollow viscera (stomach, small and large bowels)&lt;br&gt;Defect lateral to cord (usually right)&lt;br&gt;Bowel may be inflamed, thickened, matted, foreshortened&lt;br&gt;Defect size variable</td>
<td>Pranatal U/S&lt;br&gt;Elevated MS-AFP&lt;br&gt;NGT decompression&lt;br&gt;IV fluids&lt;br&gt;IV antibiotics&lt;br&gt;Keep viscera moist and protected until surgical reduction with primary abdominal closure or staged closure with silo&lt;br&gt;May have bowel dysmotility requiring motility medications</td>
<td>&gt;90% survival rate</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Omphalocele</strong>&lt;br&gt;1:5,000 live birth&lt;br&gt;Antenatal diagnosis common&lt;br&gt;Lower gestational age&lt;br&gt;Increased maternal age&lt;br&gt;M/F = 1.5:1</td>
<td>Defect of abdominal wall, with extrusion of sac covered viscera (ammon, Wharton’s jelly, peritoneum)&lt;br&gt;Duhameel’s theory – failure of body wall morphogenesis</td>
<td>Associated with genetic syndromes 30-70% (e.g. Pentolagy of Cantrell, congenital heart disease, Beckwith-Wiedemann syndrome)&lt;br&gt;Associated pulmonary hypoplasia</td>
<td>Hollow viscera (stomach, small and large bowels, often liver)&lt;br&gt;Cord on the sac</td>
<td>Pranatal U/S&lt;br&gt;Elevated MS-AFP&lt;br&gt;NGT decompression&lt;br&gt;IV fluids&lt;br&gt;IV antibiotics&lt;br&gt;Small defect (&lt;2 cm): Primary closure&lt;br&gt;Medium (2-4 cm) and large (&gt;4 cm) defects best treated with silver sulfadiazine to promote epithelialization coupled with compression dressing to allow gradual reduction, followed by future repair with or without mesh</td>
<td>40-70% survival rate&lt;br&gt;Higher survival rates most likely related to antenatal mortality of fetuses with giant omphaloceles</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bilious vomitting in infant is a life-threatening emergency secondary to midgut volvulus until proven otherwise

Rule of 2s for Meckel’s Diverticulum
- 2% of the population
- 2:1 male-to-female ratio
- Symptomatic in 2% of cases
- Found within 2 feet (10-90 cm) of the ileocecal (IC) valve
- 2 inches in length
- 2 inches in diameter
- 2 types of tissue (gastric, pancreatic)
- Often present by 2 yr of age
<table>

<th>Clinical Features and History</th>
<th>Physical Exam</th>
<th>Investigations</th>
<th>Treatment</th>
<th>Prognosis</th>
</tr>
</thead>
<tbody>
<tr>
<td>Umbilical Hernias</td>
<td>Incidence 2-14% Increases with prematurity Decreases with increasing age</td>
<td>Incomplete closure of peritoneal and fascial layers within umbilicus by 5 yr</td>
<td>Majority asymptomatic Majority spontaneously resolve by age 5 Incarceration prior to age 5 very rare Most symptoms occur in late adolescence or adulthood</td>
<td>Protrusion from umbilicus Important to differentiate from less common abdominal wall hernias that do not spontaneously resolve (e.g. epigastric hernias) Most umbilical fascial defects &gt;1.5 cm in infancy will not close spontaneously</td>
<td>None if uncomplicated</td>
<td>Repair if not spontaneously closed by age 5 Earlier repair of large “proboscis” hernias with extensive skin stretching may be warranted for cosmetic reasons Simple primary closure of fascial defect</td>
<td>Low risk of recurrence</td>
</tr>
<tr>
<td>Intestinal Atresia</td>
<td>Incidence 2-14% May be antenatally diagnosed by dilated bowel loops or “double-bubble” sign on x-ray for duodenal atresia Decreasing with increasing age</td>
<td>Duodenal – failure of bowel to recanalize after endodermal epithelium proliferation wk (8-10) Jejunal/ileal – acquired as a result of vascular disruption → ischemic necrosis → resorption of necrotic tissue → blind distal and proximal ends Colonic – mechanism unknown, thought to be similar to small bowel atresia</td>
<td>Gastric distension and vomiting (usually bilious) Duodenal – may be associated with other anomalies (tracheoesophageal fistula, cardiac, renal, and vertebral anomalies), 24-28% have Down syndrome Jejunal/ileal – within 2 d of birth, may be associated with CF Colonic – within 3 d of birth</td>
<td>Complete physical Special attention to abdominal exam Peritoneum and anus Include evaluation of respiratory distress and signs of volume depletion Congenital anomalies Jaundice</td>
<td>Contrast enema ± UGI with small bowel follow through (SBFT) Group and screen INR and PTT if for surgery</td>
<td>NPD NBT decompression Fluid resuscitate TPN Broad spectrum antibiotics Duodenal – duodenoduodenostomy or duodenoenjejunostomy Jejunal/ileal – primary anastomosis; or if atresia associated with short bowel then may create end stoma or defer surgery for bowel lengthening procedures Colonic – primary anastomosis</td>
<td>Long-term survival Duodenal – 86% Jejunal/ileal – 84% Colonic – 100%</td>
</tr>
<tr>
<td>Hirschsprung’s Disease</td>
<td>1.5,000 births M:F = 3.1 to 4:1 approaches 1:1 when whole colon involved Can have aganglionosis of small bowel as well Familial Hirschsprung’s in &lt;5% of cases</td>
<td>Defect in migration of neurocrest cells to intestine resulting in aganglionic bowel that fails to peristalsate and internal sphincter that fails to relax (internal anal sphincter achalasia) causing functional and partial mechanical obstruction, respectively; always starts in the rectum and variable involvement proximally; RET mutation</td>
<td>Failure to pass meconium spontaneously within 48 h of life is the classic history (96% of normal children should pass meconium within 24 h, and the remaining 5% within 48 h) Symptoms of bowel obstruction: abdominal distension, constipation, bilious emesis Enterocolitis/sepis Failure to thrive</td>
<td>± abdominal distension Squirt/blast sign Rectal biopsy (gold standard) – look for aganglionosis and neurohypertrophy AXR Contrast enema to find narrow rectum and transition zone Anal manometry unreliable in infants – classic finding is absence of rectoanal inhibitory reflex</td>
<td>Surgical resection of aganglionic intestinal segment and anastomosis of remaining intestine to anus Either in newborn period or staged if extensive aganglionosis</td>
<td>Surgical resection of aganglionic intestinal segment and anastomosis of remaining intestine to anus Either in newborn period or staged if extensive aganglionosis</td>
<td>Most have normal/ near-normal anorectal function Complications: Fecal incontinence and constipation, post-operative enterocolitis (medical emergency if progresses to sepsis)</td>
</tr>
<tr>
<td>Cryptorchidism</td>
<td>2.5% of term males – most of these descend spontaneously by 6 mo of age 1% of males do not spontaneously descend Idiopathic Descent is mediated by descendin which is created in response to testosterone Descent usually begins at 28 wk</td>
<td>Palpable testicle within inguinal canal or testicle which can be milked down into scrotum (called retractile tests) Occasionally no palpable testis as it is intra-abdominal Consider other congenital abnormalities</td>
<td>Bi-annual testicular exam with palpation Distinguish truly undescended testis from retractile tests (which is “high” testis due to hyperactive cremasteric muscles)</td>
<td>Depends on age of presentation US or MRI if no palpable tests Older child: LH, FSH, MIS, hCG stimulation test for gonadotropin production Infant: US, FSH, LH, karyotype, MIS, 17-hydroxyprogesterone</td>
<td>hCG to stimulate testosterone production and descent Orchidopexy – especially if undescended by age 6 mo-2 yr</td>
<td>Orchidopexy Decreased risk of torsion and blunt trauma to testicle No effect on malignant potential of testicle Descent can preserve spermatogenesis if performed by 1 yr of age 1/1,000 risk for testicular cancer (population risk is 1/4,000)</td>
<td></td>
</tr>
</tbody>
</table>
### Table 24. Pediatric Surgery (continued)

<table>
<thead>
<tr>
<th>Condition</th>
<th>Epidemiology and Risk Factors</th>
<th>Pathophysiology</th>
<th>Clinical Features and History</th>
<th>Physical Exam</th>
<th>Investigations</th>
<th>Treatment</th>
<th>Prognosis</th>
</tr>
</thead>
<tbody>
<tr>
<td>Inguinal Hernias</td>
<td>5% of all term newborns 2x risk and more likely bilateral if pre-term M:F = 4:1 Low birth weight increases risk 1/5 inguinal hernias will become incarcerated if patient is &lt; 1 yr old Incarceration is more common in females Associated with other conditions: androgen insensitivity, connective tissue diseases</td>
<td>All infant hernias are indirect: descent of intra-abdominal contents through the internal inguinal ring through a patent tunica vaginalis</td>
<td>Most common presentation: painless intermittent mass in groin, may also note extension into scrotum (scrotal mass in absence of inguinal mass is a hydrocele) If incarcerated: tender; vomiting, firm mass, erythema then cyanosis of mass may be noted</td>
<td>Palpate for “bag of worms” suggests possible testicular varicocele Biannual testicular exam + palpation along inguinal canal to evaluate for any masses “Silk sign” — palpable thickening of cord Mass palpated at external inguinal ring and reducible through inguinal canal into abdomen Must always try reduction to confirm that hernia is not incarcerated</td>
<td>Physical exam is gold standard U/S only if physical exam uncertain (e.g. in small infants where exam can be difficult)</td>
<td>Manual reduction — to relieve acute symptoms Hemororhaphy — definitive treatment by reduction of herniated contents and high ligation of sac for indirect hernias Laparoscopic or open techniques</td>
<td>Risk of recurrence after surgical reduction &lt; 3% but higher if repair done in premature infants or if hernia was incarcerated/strangulated</td>
</tr>
<tr>
<td>Intussusception</td>
<td>Most common cause of bowel obstruction between the ages of 6-36 mo 26/100,000 newborns M:F = 2:2 Pathologic lead points: enlarged Peyer’s patches due to viral infections of the GI tract, polypos, Meckel’s diverticulum CF, lymphoma, IBD may increase risk</td>
<td>Idiopathic is most common Usually starts at ileocecal junction Telescoping of bowel into itself causing an obstruction and vascular compromise</td>
<td>Acute onset of abdominal pain which is classic episodic “colicky” pain Vomiting = bilious Abdominal mass Current-jelly stool suggests mucosal necrosis and sloughing</td>
<td>Abdominal exam Palpate for masses (especially sausage shaped upper abdominal mass) and tenderness Signs of bowel obstruction: distended abdomen Look for localized peritonitis which suggests transmural ischemia</td>
<td>AXR for signs of bowel obstruction or perforation U/S if suspect pathology</td>
<td>If peritonitis, then consider operative management Non-operative management involves reduction via air contrast enema Operative reduction can be done open or laparoscopically Resection of involved colon if failure to reduce or bowel appears compromised</td>
<td>10% recurrence rate If recurrent = more likely non-idiopathic In successfully reduced by enema in older children allow 2 wk resolution of edema then perform SBFT to rule out pathologic lead points</td>
</tr>
<tr>
<td>Tracheoesophageal Fistula (TEF)</td>
<td>Associated anomalies in 50%: VACTERL association (see Pediatrics: P42)</td>
<td>Varies with type of fistula May have history of maternal polyhydramnios May present after several months (if no associated esophageal atresia) of non-bilious vomiting, coughing, cyanosis with feeds, respiratory distress, recurrent pneumonia, frothy bubbles of mucus in mouth and nose that return after suctioning</td>
<td>X-ray: anatomic abnormalities, NGT curled in pouch</td>
<td>Investigate for other congenital anomalies, early repair by surgical ligation to prevent lung damage and maintain nutrition and growth</td>
<td>Complications: pneumonia, sepsis, reactive airways disease Following repair: esophageal stenosis and strictures at repair site, GERD, and poor swallowing (i.e. dysphagia, regurgitation)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Skin Lesions

- see Dermatology, D5; Emergency Medicine, ER17; Plastic Surgery, PL5
Common Medications

Antiemetics
- dimenhydrinate (Gravol®) 25-50 mg PO/IM q4-h pm
- prochlorperazine (Stemetil®) 5-10 mg PO/IM bid-tid pm
- metoclopramide (Maxeran®) 10 mg IV/mq q2-3-h pm, 10-15 mg PO qid (30 min before meals and qhs)
- ondansetron (Zofran®) 4-8 mg PO q8-h pm
- granisetron (Kytril®) 1 mg PO bid (for nausea from chemotherapy/radiation)

Analgesics
- acetaminophen + codeine (Tylenol® #3/plain) 1-2 tabs q4-6-h PO/PR pm
- hydromorphone i+iv tabs PO q4-h pm, 0.5-2 mg IV q3-4-h pm
- ibuprofen 200-400 mg PO q4-h pm
- morphine 2.5-10 mg IM/SC q4-h pm + 1-2 mg IV q1-h pm for breakthrough
- ketorolac (Fortadol®) 30-60 mg IM/IV q6-h pm
- Percoct® (acetaminophen/oxycodeone, 325/5 mg) 1-2 tabs PO q4-h pm

DVT Prophylaxis
- heparin 5,000 units SC bid, if cancer patient then heparin 5,000 units SC tid
- dalfopristin (Fragmin®) 5,000 units SC daily
- enoxaparin (Lovenox®) 40 mg SC daily

Antidiarrheals
- loperamide (Imodium®) 4 mg PO initially, then 2 mg PO after each loose stool up to 16 mg/d
- diphenoxylate + atropine (Lomotil®) 2 tabs/10 mL PO qid

Laxatives
- sennosides (Senokot®) 1-2 tabs qhs
- docusate sodium (Colace®) 100 mg PO bid
- glycerine suppository 1 tab PR pm
- lactulose 15-30 mL PO qid pm
- milk of magnesia (MOM) 30-60 mL PO qid pm
- bisacodyl (Dulcolax®) 10-15 mg PO daily

Sedatives
- zopiclone (Imovane®) 5-7.5 mg PO qhs pm
- lorazepam (Ativan®) 0.5-2 mg PO/SL qhs pm

Antibiotics
- cefazolin (Ancef®) 1 g IV/IM on call to OR or q8-h – GP except Enterococcus, GN only E. coli, Klebsiella, and Proteus
- cefalexin (Keflex®) 250-500 mg PO qid – Listeria, GP except Enterococcus, GN only E. coli, Klebsiella, and Proteus
- ceftriaxone 1-2 g IV/mq q4-h – broad coverage including Pseudomonas
- ampicillin 1-2 g IV q4-h – Listeria, GP (Enterococcus) except Streplococcus and E. coli, oral anaerobes
- except Bacteroides
- gentamicin 3.5 mg/kg/d IV/IM divided q8-h; monitor creatinine, gentamicin levels – GN including Pseudomonas
- ciprofloxacin 400 mg IV q12-h, 500 mg PO bid – GN including Pseudomonas
- metronidazole (Flagyl®) 500 mg PO/IV bid (500 mg PO tid for C. difficile) – anaerobes
- clindamycin 600-900 mg IV q8-h, 150-400 mg PO qid – GP except Enterococcus, anaerobes
- piperacillin/tazobactam 4.5 mg IV q6-h – GP, GN, and anaerobes
- vancomycin 1g IV q2-h – GP and MRSA
- sulfamethoxazole/trimethoprim DS (Septra®) PO bid – GP, GN including noncardiac

Over-the-Counter Medications
- Pepso-Bismol® (bismuth subsalicylate) 2 tabs or 30 mL PO q30min-1h up to 8 doses/d
- side effects: black stools, risk of Reyes’s syndrome in children
- Alka-Seltzer® (ASA + citrate + bicarbonate) 2 tabs in 4 oz water PO q4-h pm, max 8 tabs
- Maalox® (aluminum hydroxide + magnesium hydroxide) 10-20 mL or 1-4 tabs PO pm
- Tums® (calcium carbonate) 1-3 g PO q2-h pm
- Rolaid® (calcium carbonate and magnesium hydroxide) 2-4 tabs PO q1h pm, max 12 tabs/d

Death in the United States. NCHS Data Brief 2009;No64:2011

Physiology and Pathology of Aging

Definition

• major categories of impairment that appear with old age and affect the physical, mental, and social domains of the elderly, usually due to many predisposing and precipitating factors, rather than a single cause

Table 2. Changes Occurring Frequently with Aging

<table>

Differential Diagnoses of Common Presentations

Constipation

- see Gastroenterology, G24

Definition
- less than 3 bowel movements in one week and/or hard stools, straining, sense of blockade, needing manual maneuvers or incomplete evacuation on more than 25% of occasions for at least 12 wk (does not need to be consecutive)

Epidemiology
- chronic constipation increases with age (up to 1/3 of patients >65 yr experience constipation)

Pathophysiology
- impaired rectal sensation (increased rectal distention required to stimulate the urge to defecate)
- colorectal dysmotility

Treatment
- non-pharmacological
  - increase fiber intake
  - ensure adequate fluid intake
  - discourage chronic laxative use
  - engage in regular exercise
  - review medication regime, reduce dosages or substitute
- pharmacologic
  - see Common Medications, GM15

Risk Factors for Constipation in the Elderly Include:
- Immobility
- Diet: low fiber/calorie diet, dehydration
- Medications:
  - Polypharmacy
  - Drugs: narcotics, calcium channel blockers, anticholinergics
  - GI: obstructive lesions (bowel obstruction, cancer, diverticular disease, IBD, strictures, uterine prolapse), altered colonic motility (IBS, colonic inertia)
- Neurological: spinal cord injury, Parkinson’s disease, stroke, autonomic dysfunction
- Metabolic: diabetes, hypokalemia, hypercalcemia
- Psychiatric: depression, dementia

Figure 1. Treatment algorithm for the management of chronic constipation in the elderly
Adapted from: Clin Interv Aging 2010;5:163-171

Delirium, Dementia, and Depression

- see Psychiatry, PS16, PS17, PS7 and Neurology, N19

Definition
- pathologic decrease in memory, language, or executive function

Differential Diagnosis
- delirium, dementia, or pseudodementia of depression
Table 3. Differentiating the Three Ds of Cognitive Impairment

<table>
<thead>
<tr>

<td>Self-deprecatory</td>
</tr>
</tbody>
</table>

Delirium Prevention in Elderly
- ensure optimal vision and hearing to support orientation (e.g. appropriate eyewear and hearing aids)
- provide adequate nutrition and hydration (up in chair to eat and drink whenever feasible)
- encourage regular mobilization to build and maintain strength, balance, and endurance
- avoid unnecessary medications and monitor for drug interactions
- avoid bladder catheterization if possible
- ensure adequate sleep

Elder Abuse

Definition
- includes physical abuse, sexual abuse, emotional/psychological abuse, financial abuse, abandonment, and neglect
- in the U.S., most states have criminal penalties for elder abuse

Epidemiology
- in the U.S., estimates of the frequency of elder abuse range from 3-8%
- insufficient evidence to include/exclude screening in the Periodic Health Exam

Risk Factors

Table 4. Risk Factors for Elder Abuse

Caregiver Abuse Screen (CASE)
• instructions
  ▪ to be answered by caregivers, if answer “yes” to a question, further explore issue
  ▪ the more “yes” responses, the more likely the presence of abuse
• screening tool
  ▪ please answer the following questions as a helper/caregiver
    1. Do you sometimes have trouble making ______ control his/her temper or aggression?
    2. Do you often feel you are being forced to act out of character/do things you feel badly about?
    3. Do you find it difficult to manage ______’s behavior?
    4. Do you sometimes feel that you are forced to rough with ______?
    5. Do you sometimes feel that you can’t do what is really necessary or what should be done for ______?
    6. Do you often feel you have to reject/ignore ______?
    7. Do you often feel so tired and exhausted that you cannot meet ______’s needs?
    8. Do you often feel you have to yell at ______?

From: NICE. Case: Caregiver Abuse Screen. 2010. Reproduced with permission from NICE

Management
• assess safety and determine capacity to make decisions about living arrangements
• establish need for hospitalization or alternate accommodation (e.g. immediate risk of physical harm by self or caregiver)
• involve multidisciplinary team (e.g. nurse, social worker, family members, and physicians including geriatrician, psychiatrist or family physician)
• educate and assist caregiver, contact local resources (e.g. legal aid, crisis support, PSW, caregiver support groups)
• interpret critical and lab findings that are key in exclusion, differentiation and diagnosis

Falls

Epidemiology
• 30-40% of people >65 yr old and ~50% of people >80 yr old fall each yr
  ▪ equally common between men and women, but more likely to result in injury in women
  ▪ 5% of falls lead to hospitalization
  ▪ falls are the leading cause of death in injury in persons older than 65 yr
  ▪ 25% associated with serious injuries (e.g. hip fracture, head injury, bruises, laceration)
  ▪ between 25-75% do not recover to previous level of ADL function
  ▪ mortality increases with age (171/100,000 in men >85 yr old) and type of injury (25% with hip fracture die within 6 mo)

Etiology
• multifactorial
  • extrinsic
    ▪ environmental (e.g. home layout, lighting, stairs, footwear), accidental, abuse
    ▪ medications/substances (e.g. alcohol)
    ▪ acute illness, exacerbation of chronic illness
  • intrinsic
    ▪ orthostatic/syncopal
    ▪ age-related changes and diseases associated with aging: musculoskeletal (arthritis, muscle weakness), sensory (visual, proprioceptive, vestibular), cognitive (depression, dementia, delirium, anxiety), cardiovascular (CAD, arrhythmia, MI, low BP), neurologic (stroke, decreased LOC, gait disturbances/ataxia), metabolic (glucose, electrolytes)

Investigations
• directed by history and physical
• comprehensive geriatric assessment to identify all potential causes
• CBC, electrolytes, BUN, creatinine, glucose, Ca²⁺, TSH, B₁₂, urinalysis, cardiac enzymes, ECG, CT head

Prevention
• multidisciplinary, multifactorial, health, and environment risk factor screening and intervention programs in the community
• muscle strengthening, balance retraining, and group exercise programs (e.g. tai chi)
• home hazard assessment and modification (e.g. remove rugs, add shower bars, etc.)
• prescription of vitamin D 1000 IU daily
• tapering or gradually discontinuation of psychotropic medication
• postural hypotension, heart rate, and rhythm abnormalities management
• eyesight and footwear optimization

Red Flags for Elder Abuse
• Delay in seeking medical attention
• Disparity in histories
• Implausible or vague explanations
• Frequent emergency room visits for exacerbations of chronic disease despite plan for medical care and adequate resources
• Presentation of functionality impaired patient without designated caregiver
• Lab findings inconsistent with history

Key Physical Findings in the Elderly Patient Who Falls or Nearly Falls

I HATE FALLING
Inflammation of joints
Hypotension (orthostatic changes)
Auditory and visual abnormalities
Tremor
Equilibrium (balance) problem
Foot Problems
Arrhythmia, heart block or valvular disease
Leg-length discrepancy
Lack of conditioning (generalized weakness)
Illness
Nutrition
Gait disturbance

A history of falls within the past 1-2 yr is a predictor of motor vehicle crashes in the older population. These patients should be evaluated on their ability to drive and counseled about driving.

Drugs That May Increase the Risk of Falling
• Sedative-hypnotic and anxiolytic drugs (especially long-acting benzodiazepines)
• Antidepressants (including MAOIs, SSRIs, TCAs)
• Antipsychotics and tranquilizers (phenothiazines and butyrophenones)
• Antihypertensive drugs
• Antiarrhythmics (Class IA)
• Diuretics
• Systemic corticosteroids
• NSAIDs
• Anticholinergic drugs
• Hypoglycemic agents
• Alcohol

Frailty (Failure to Thrive)

Definition
- declining independence and functional capacity with loss of energy, vigor, and/or weight in older adults
- not an inevitable consequence of aging

Etiology
- malnutrition, functional impairment, cognitive impairment, and depression
Incontinence

**Fecal Incontinence**

**Epidemiology**
- Second leading cause of nursing home placement

**Etiology**
- Commonly multifactorial
  - Structural abnormalities
  - Trauma (e.g., prior vaginal delivery, surgery)
  - Prolapse
  - Tumor/trauma (e.g., brain, spinal cord, cauda equina)
- Functional abnormalities
  - Neurologic conditions – neuropathy, multiple sclerosis, stroke, dementia
- Others
  - Constipation with overflow may be a factor
  - Psychosis (willful soiling)
  - Age >80 yr: decreased external sphincter strength and weak anal squeeze, increased rectal compliance, decreased resting tone and internal sphincter, impaired anal sensation
- Medications (e.g., laxatives, anticholinergics, antidepressants, caffeine, muscle relaxants)

**Investigations (if cause not apparent from history and physical)**
- Differentiate true incontinence from frequency and urgency (i.e., IBS, IBD)
- Stool studies
- Anal or rectal ultrasound
- Colonoscopy, sigmoidoscopy, anoscopy
- Anorectal manometry or functional testing

**Management**
- Diet/bulking agent if stool is liquid or loose
- Disimpaction, prevent impaction
- Anti-diarrheal agents (e.g., loperamide)
- Regular defecation program in patients with dementia
- Counsel about biofeedback therapy (retraining of pelvic floor muscles)
URINARY INCONTINENCE

- see Urology, U5

Epidemiology

- 15-30% prevalence dwelling in community and at least 50% of institutionalized seniors
- morbidity: cellulitis, pressure ulcers, urinary tract infections, falls with fractures, sleep deprivation, social withdrawal, depression, sexual dysfunction
- not associated with increased mortality

Pathophysiology

- not a normal part of aging, urinary incontinence is a loss of control due to a combination of:
  - genitourinary pathology: increased post-void residual volume, increased involuntary bladder contractions (urge incontinence)
  - age-related changes: decreased bladder capacity
  - comorbid conditions and medications
  - functional impairment
- in elderly women: decline in bladder outlet and urethral resistance pressure promoting stress incontinence
- in elderly men: prostatic enlargement can cause overflow and urge incontinence

Gait Disorders

- see Neurology, N34

Hazards of Hospitalization

Table 6. Recommendations for Sequelae of Hospitalization in Older Patients

<table>
<thead>
<tr>
<th>Sequelae</th>
<th>Recommendations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Malnutrition</td>
<td>No dietary restrictions (except diabetes), assistance, dentures if necessary, sitting in a chair to eat</td>
</tr>
<tr>
<td>Urinary incontinence</td>
<td>Medication review, remove environmental barriers, discontinue use of catheter</td>
</tr>
<tr>
<td>Depression</td>
<td>Routine screening</td>
</tr>
<tr>
<td>Adverse drug event</td>
<td>Medication review</td>
</tr>
<tr>
<td>Confusion/delirium</td>
<td>Orientation, visual and hearing aids, volume repletion, noise reduction, early mobilization, medication review, remove restraints</td>
</tr>
<tr>
<td>Pressure ulcers</td>
<td>Low-resistance mattress, daily inspection, repositioning every 2 h</td>
</tr>
<tr>
<td>Infection</td>
<td>Early mobilization, remove unnecessary IV lines, catheters, NG tubes</td>
</tr>
<tr>
<td>Falls</td>
<td>Appropriate footwear, assistive devices, early mobilization, remove restraints, medication review</td>
</tr>
<tr>
<td>Hypotension/dehydration</td>
<td>Early recognition and repletion</td>
</tr>
<tr>
<td>Diminished aerobic capacity/loss of muscle strength/contractures</td>
<td>Early mobilization</td>
</tr>
<tr>
<td>Decreased respiratory function</td>
<td>Incentive spirometry, physiotherapy</td>
</tr>
</tbody>
</table>

Hypertension

- see Family Medicine, FM35
- 60-80% of elderly (>65 yr old) have HTN
  - 60% of these have isolated systolic HTN
  - the benefit of treating HTN in the elderly is 2-4 times greater than that achieved in the treatment of younger patients with primary HTN
  - systolic and pulse pressure are major predictors of outcome in the elderly patient
  - in older adults, base treatment on sBP
  - target BP: sBP <140, dBP <90; for patients with DM: sBP <130, dBP <80
  - more recently, some argue a target of sBP <140 reasonable for all elderly patients, and minimizes risk of hypertension
- treatment:
  - non-pharmacologic treatments are first-line, then thiazide monotherapy is recommended
  - add ACEI/ARB if also atherosclerosis, DM, CHF or chronic kidney disease
  - add β-blockers if also angina or CHF
**Immobility**

**Complications**
- cardiovascular: orthostatic hypotension, venous thrombosis, embolism
- respiratory: decreased ventilation, atelectasis, pneumonia
- gastrointestinal: anorexia, constipation, incontinence, dehydration, malnutrition
- genitourinary: infection, urinary retention, bladder calculi, incontinence
- musculoskeletal: atrophy, contractures, bone loss
- skin: pressure ulcers
- psychological: sensory deprivation, delirium, depression

**Immunizations**

- the following immunizations are recommended for people 65 yr of age and older
  - tetanus: every 10 yr
  - pneumococcus: every 5 yr
  - influenza: every autumn
  - herpes zoster: Zostivax

**Malnutrition**

**Definition**
- involuntary weight loss of ≥5% baseline body weight or ≥5 kg
- hypoalbuminemia, hypocholesterolemia

**Etiology**
- nutritional
  - decreased assimilation: impaired transit, maldigestion, malabsorption
  - decreased intake: financial, psychiatric (depression), cognitive deficits, anorexia associated with chronic disease, functional deficits (e.g. difficulty shopping, preparing meals or feeding oneself due to functional impairment)
- stress: acute or chronic illness/infection, chronic inflammation, abdominal pain
- mechanical: dental problems, dysphagia
- age-related changes: appetite dysregulation, decreased thirst
- mixed: increased energy demands (e.g. hyperthyroidism), abnormal metabolism, protein-losing enteropathy

**Clinical Features**
- history
  - recent or chronic illness
  - depression, GI symptoms
  - functional disability: impaired ADLs and IADLs
  - social factors: economic barriers, dental problems and living situation (e.g. living alone)
  - constitutional symptoms (e.g. recent weight loss)
- physical exam
  - BMI <23.5 in males, <22 in females should raise concern
  - temporal wasting, muscle wasting, presence of triceps skin fold
  - assess cognition

**Investigations**
- CBC, electrolytes, Ca²⁺, Mg²⁺, PO₄³⁻, creatinine, LFTs (albumin, INR, bilirubin), B₁₂, folate, TSH, transferrin, lipid profile, urinalysis, ESR, CXR

**Osteoporosis**

- see Endocrinology E42

**Presbycusis**

- see Otolaryngology OT20
Pressure Ulcers

- see Plastic Surgery, PL16

Risk Factors
- extrinsic factors: friction, pressure, shear force
- intrinsic factors: immobility, malnutrition, moisture, sensory loss

Table 7. Classification of Pressure Ulcers

| Stage I | Changes include skin temperature, tissue consistency or sensation
| An area of persistent erythema in lightly pigmented, intact skin; in darker skin, it may appear red, blue or purple |
| Stage II | Partial thickness skin loss involving the epidermis, dermis or both
| The ulcer is superficial and presents as an abrasion, blister or shallow crater |
| Stage III | Full thickness skin loss involving damage or necrosis of subcutaneous tissue which may extend down to, but not through, underlying fascia
| Presents as a deep crater with or without undermining of adjacent tissue |
| Stage IV | Full thickness skin loss with extensive destruction, tissue necrosis or damage to muscle, bone or supporting structures
| May have associated undermining and/or sinus tracts |

Prevention
- pressure reduction
  - frequent repositioning
  - pressure-reducing devices (static, dynamic)
- maintaining nutrition, encouraging mobility and managing incontinence

Treatment
- optimize nutritional status
- minimize pressure on wound
- analgesia
- wound debridement (mechanical, enzymatic, autolytic) and dressing application
- maintain moist wound environment to enable re-epithelialization
- treatment of wound infections (topical gentamicin, silver sulfadiazine, mupirocin)
- swab wounds not demonstrating clinical improvement for C&S; biopsy chronic wounds to rule out malignancy
- stage IV ulcers typically warrant surgical debridement
- consider other treatment options
  - negative pressure wound therapy/vacuum-assisted closure (VAC)
  - biological agents: application of fibroblast growth factor, platelet-derived growth factor to wound
  - non-contact normothermic wound therapy
  - electrotherapy

Driving Competency

Reporting Requirements
- not an issue unique to geriatrics – any patient may suffer from a medical condition that impairs their ability to drive should be reported
- in the U.S., varies by state

Conditions that may Impair Driving

Table 8. Conditions that Impair Driving

| Alcohol | Patients with history of impaired driving and those with high probability of future impaired driving should not drive until further assessed
| Alcohol dependence or abuse: if suspected, should be advised not to drive
| Alcohol withdrawal seizure: must complete a rehabilitation program and remain abstinent and seizure-free for 6 mo before driving |
| Blood Pressure | HTN: sustained BP > 170/110 should be evaluated carefully
| Hypotension: if syncopeal, discontinue until attacks are treated and preventable |
### Table 8. Conditions that Impair Driving (continued)

<table>
<thead>
<tr>
<th>Condition</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cardiovascular Disease</td>
<td>Suspected asymptomatic CAD or stable angina: no restrictions</td>
</tr>
<tr>
<td></td>
<td>STEMI, NSTEMI with significant LV damage, coronary artery bypass surgery: no driving for one month following hospital discharge</td>
</tr>
<tr>
<td></td>
<td>NSTEMI with mild LV damage, unstable angina: no driving for 48 h if percutaneous coronary intervention (PCI) performed or 7 d if no PCI performed</td>
</tr>
<tr>
<td>Cerebrovascular Conditions</td>
<td>TIA: should not be allowed to drive until a medical assessment is completed</td>
</tr>
<tr>
<td></td>
<td>Stroke: should not drive for at least one month; may resume driving if functionally able; no clinically significant motor, cognitive, perceptual or vision deficits; no obvious risk of sudden recurrence; underlying cause appropriately treated; no post-stroke seizure</td>
</tr>
<tr>
<td>COPD</td>
<td>Mild/moderate impairment; no restrictions</td>
</tr>
<tr>
<td></td>
<td>Moderate or severe impairment requiring supplemental oxygen: road test with supplemental oxygen</td>
</tr>
<tr>
<td>Cognitive Impairment/Dementia</td>
<td>Moderate to severe dementia is a contraindication to driving; defined as the “inability to independently perform 2 or more IADLS or any basic ADL”</td>
</tr>
<tr>
<td></td>
<td>Patients with mild dementia should be assessed; if indicated, refer to specialized driving testing center; if deemed fit to drive, re-evaluate patient every 6-12 mo</td>
</tr>
<tr>
<td></td>
<td>Poor performance on MMSE, clock drawing or Trails B suggests a need to investigate driving ability further</td>
</tr>
<tr>
<td></td>
<td>MMSE score alone (whether normal or low) is insufficient to determine fitness to drive</td>
</tr>
<tr>
<td>Diabetes</td>
<td>Diet controlled or oral hypoglycemic agents: no restrictions in absence of diabetes complications that may impair ability to drive (e.g. retinopathy, nephropathy, neuropathy, cardiovascular or cerebrovascular disease)</td>
</tr>
<tr>
<td></td>
<td>Insulin use: may drive if no complications (as above) and no severe hypoglycemic episode in the last 6 mo</td>
</tr>
<tr>
<td>Drugs</td>
<td>Be aware of: analgesics, anticholinergics, anticonvulsants, antidepressants, antipsychotics, opiates, sedatives, stimulants</td>
</tr>
<tr>
<td></td>
<td>Degree of impairment varies: patients should be warned of the medication/withdrawal effect on driving until condition resolves</td>
</tr>
<tr>
<td>Hearing Loss</td>
<td>Effect of impaired hearing on ability to drive safely is controversial</td>
</tr>
<tr>
<td></td>
<td>Acute labyrinths, positional vertigo with horizontal head movement, recurrent vertigo: advise not to drive until condition resolves</td>
</tr>
<tr>
<td>Musculoskeletal Disorders</td>
<td>Physician’s role is to report etiology, prognosis and extent of disability (pain, range of motion, coordination, muscle strength)</td>
</tr>
<tr>
<td>Post-Operative</td>
<td>Outpatient, conscious sedation: no driving for 24 h</td>
</tr>
<tr>
<td></td>
<td>Outpatient, general anesthesia: no driving for ≥24 h</td>
</tr>
<tr>
<td>Seizures</td>
<td>First, single, unprovoked: no driving for 3 mo until complete neurologic assessment, EEG, CT head Epilepsy: can drive if seizure-free on medication and physician has insight into patient compliance</td>
</tr>
<tr>
<td>Sleep Disorders</td>
<td>If patient is believed to be at risk due to a symptomatic sleep disorder but refuses investigation with a sleep study or refuses appropriate treatment, the patient should not drive</td>
</tr>
<tr>
<td>Visual Impairment</td>
<td>Visual acuity: contraindicated to drive if &lt;20/50 with both eyes examined simultaneously</td>
</tr>
<tr>
<td></td>
<td>Visual field: contraindicated to drive if &lt;120° along horizontal meridian and 15° continuous above and below fixation with both eyes examined simultaneously</td>
</tr>
</tbody>
</table>

N.B. guidelines included refer specifically to private driving.

### Health Care Institutions

#### Table 9. Classification of Health Care Services and Institutions

<table>
<thead>
<tr>
<th>Institution/Service</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Home Health Agency</td>
<td>Health care services offered at home for those who can live independently at home or under the care of family members including professional health care services, personal care and support (ADL), homemaking, support services such as transportation, meal delivery, day programs, caregiver relief, security checks, etc.</td>
</tr>
<tr>
<td>Residential</td>
<td>Divided into short (&lt;60-90 d/yr) and long (indefinite) stay</td>
</tr>
<tr>
<td>a) Seniors Affordable Housing</td>
<td>Seniors who live independently and manage their own care but prefer to live near other seniors; usually has accessibility features and rent is adjusted based on income</td>
</tr>
<tr>
<td>b) Retirement/Nursing Home</td>
<td>Residents are fairly independent and require minimal support with ADLs and IADLs; often privately owned</td>
</tr>
<tr>
<td>c) Supportive Housing</td>
<td>Residents require minimal to moderate assistance with daily activities while living independently; often rental units in an apartment and may offer some physiotherapy and rehabilitation services</td>
</tr>
<tr>
<td>d) Long-term Care/Skilled Nursing Facility</td>
<td>Around the clock nursing care and on-call physician coverage; often offers occupational therapy, physiotherapy, respiratory therapy, and rehabilitation services; may be used short-term for caregiver respite, or for supportive patient care to regain strength and confidence after leaving the hospital</td>
</tr>
<tr>
<td>e) Hospice</td>
<td>Free-standing facility or designated floor in a hospital or nursing home for care of terminally ill patients and their families; focus is on quality of life and often requires prognosis ≤3 mo</td>
</tr>
</tbody>
</table>
names of community health care institutions, types of facilities, and services offered vary between geographical locations
factors to consider when seeking services/institutions include level of care required, support networks, duration of stay, and cost

Palliative and End-of-Life Care

Principles and Quality of Life

- support, educate, and treat both patient and family
- address physical, psychological, social and spiritual needs
- focus on symptom management and comfort measures
- offer therapeutic environment and bereavement support
- ensure maintenance of human dignity

End-of-Life Care Discussions

When to Initiate End-of-Life Care Discussions
- recent hospitalization for serious illness
- severe progressive medical condition(s)
- death expected within 6-12 mo
- patient inquires about end-of-life care

Suggested Topics for Discussion
- goals of care (disease vs. symptom management)
- advance directives, power of attorney, public guardian and trustee
- treatment options and likelihood of success
- common medical interventions
  - mechanical ventilation
  - antibiotic therapy
  - feeding tubes
- resuscitation options and likelihood of success (Full Code vs. DNR status including preferences for CPR, intubation, ICU admission, artificial hydration)

Power of Attorney

- see Ethical, Legal, and Organizational Medicine, ELOAM8

Instructional Advance Directives

- see Ethical, Legal, and Organizational Medicine, ELOAM8

Symptom Management

Assessment Tools
- Edmonton Symptom Assessment System (ESAS): a tool that asks patients to rate the intensity of symptoms from 0-10 and allows for tracking of the efficacy of interventions. Assesses: pain, tiredness, nausea, depression, anxiety, drowsiness, appetite, well being, shortness of breath, and “other problem”
- Palliative Performance Scale (PPS): a tool that uses functional status to predict survival in terminally ill patients. Assesses 5 components: ambulation, activity and evidence of disease, self-care, intake and conscious level

Source: J Pain Palliat Care 1991;7:6-9 and Victoria Hospice Society 2006;120-121
**Geriatric Pharmacology**

### Pharmacokinetics

#### Table 11. Age-Associated Pharmacokinetics

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Age Effect</th>
<th>Implications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Absorption (less</td>
<td>Increased gastric pH, decreased splanchic blood flow, GI absorptive surface</td>
<td>Drug-drug and drug-food interactions are more likely</td>
</tr>
<tr>
<td>significant)</td>
<td>and dermal vascularity; delayed gastric emptying</td>
<td>to affect absorption</td>
</tr>
<tr>
<td>Distribution</td>
<td>Increased total body fat and α1-glycoprotein</td>
<td>Lipophilic drugs have a larger volume of distribution</td>
</tr>
<tr>
<td>Metabolism (less</td>
<td>Decreased lean body mass, total body water and albumin</td>
<td>Decreased binding of acidic drugs, increased binding</td>
</tr>
<tr>
<td>significant)</td>
<td>Impaired phase I reactions (oxidative system)</td>
<td>of basic drugs</td>
</tr>
<tr>
<td>Elimination</td>
<td>Decreased renal blood flow, GFR, tubular secretion and renal mass</td>
<td>For every % reduction in clearance, decrease the dose</td>
</tr>
</tbody>
</table>

---

**WHO’s Pain Relief Ladder**

- **Opioid for moderate to severe pain ± Non-opioid ± Adjuvant**
- **Pain persisting or increasing**

**Opioid Equivalent Doses (to 10 mg of IV morphine)**

<table>
<thead>
<tr>
<th>Opioid</th>
<th>SC/IV dose</th>
<th>PO dose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Morphine</td>
<td>10 mg</td>
<td>20-30 mg</td>
</tr>
<tr>
<td>Codeine</td>
<td>Not recommended</td>
<td>180-240 mg</td>
</tr>
<tr>
<td>Oxycodone</td>
<td>Not recommended</td>
<td>10-15 mg</td>
</tr>
<tr>
<td>Hydromorphone</td>
<td>2 mg</td>
<td>4-6 mg</td>
</tr>
<tr>
<td>Fentanyl transdermal</td>
<td>25 µg/h = morphine 90 mg</td>
<td>PO/24 h, however fentanyl takes 12-16 h to reach steady state</td>
</tr>
</tbody>
</table>

---

**Death Rattle**

Noise caused by the oscillatory movement of mucous secretions in the upper airway with inspiration and expiration

**Nociceptive Pain**

Somatic: localized to bone/skin/joint/muscle; gnawing, dull pain
Visceral: not well localized; crampy pain, pressure

**Neuropathic Pain**

Burning, shooting, radiating pain; localized to dermatomal regions

---

Serum creatinine does not reflect creatinine clearance in the elderly, as they can have falsely lowered serum creatinine levels. Some advocate for rounding geriatrics’ patients low serum creatinine numbers to 1 mg/dL, however this is controversial.
Pharmacodynamics

Drug Sensitivity
• changes in pharmacokinetics as well as intrinsic sensitivity lead to altered drug responses
• increased sensitivity to warfarin, sedatives, antipsychotics, digoxin and narcotics
• decreased sensitivity to β-blockers in majority of elderly patients, though some may have increased sensitivity

Decreased Homeostasis
• poorer compensatory mechanisms leading to more adverse reactions (e.g. bleeding with NSAIDs/anticoagulants, altered mental status with anticholinergic/sympathomimetic/anti-Parkinsonian drugs)

Polypharmacy

Definition
• prescription, administration or use of five or more medications at the same time

Epidemiology
• patients over 65 years old are the largest medication consumers in the United States
• many elderly patients do not understand their medications
• hospitalized elderly are given an average of 10 medications during admission

Risk Factors for Non-Compliance
• risk of non-compliance correlates with medication factors, not age
  ▪ number of medications – compliance with 1 medication is 80%, but drops to 25% with ≥6 medications
• increased dosing frequency, complicated container design, financial constraints, and cognitive impairment

Adverse Drug Reactions
• any noxious or unintended response to a drug that occurs at doses used for prophylaxis or therapy
• risk factors in the elderly
  ▪ intrinsic: comorbidities, age-related changes in pharmacokinetics and pharmacodynamics
  ▪ extrinsic: number of medications, multiple prescribers, unreliable drug history
• 90% of ADRs are from: ASA, analgesics, anticoagulants, antimicrobials, antineoplastics, digoxin, diuretics, hypoglycemics, steroids

Preventing Polypharmacy
• consider drug: safer side effect profiles, convenient dosing schedules, convenient route, efficacy
• consider patient: other medications, clinical indications, medical comorbidities
• consider patient-drug interaction risk factors for ADRs
• review drug list regularly to eliminate medications with no clinical indication or with evidence of toxicity
• avoid treating an ADR with another medication

Inappropriate Prescribing in the Elderly

Epidemiology
• the estimated prevalence of potentially inappropriate prescribing ranges from 12-40%

Beers Criteria
• a list of medications to avoid in adults 65 and older due to safety concerns
• examples include long-acting benzodiazepines, strong anticholinergics, high-dose sedatives
• the elderly are also often under-treated (ACEI, ASA, β-blockers, thrombolytics, warfarin)

Beers Criteria of Choice in the Elderly
LOT
Lorazepam
Oxazepam
Temazepam

Approach to Medication Review in the Elderly
NO TEARS
Need and indication
Open-ended questions (to get patient’s perspective on medications)
Tests and monitoring (to assess disease control)
Evidence and guidelines
Adverse events
Risk reduction (of adverse events such as falls)
Simplification/switches

New medications: Start Low, Go Slow!

Principles for Prescribing in the Elderly
CARED
Caution/Compliance
Age (adjust dosage for age)
Review regimen regularly
Educate
Discontinue unnecessary medications

Adverse drug reactions in the elderly may present as delirium, falls, fractures, urinary incontinence/retention or fecal incontinence/impaction

Beers Criteria
For full list of medications, consult the following reference:
The American Geriatrics Society 2012 Beers Criteria Update Expert Panel
J Am Geriatr Soc 2012;60(4):616-31
http://www.americangeriatrics.org

**Acronyms**

- β-HCG: beta-human chorionic gonadotropin
- AFP: alpha-fetoprotein
- AIS: androgen insensitivity syndrome
- ASCUS: atypical squamous cells of undetermined significance
- AUB: abnormal uterine bleeding
- BMI: body mass index
- BSO: bilateral salpingo-oophorectomy
- BV: bacterial vaginosis
- CMV: cytomegalovirus
- DCS: dilatation and curettage
- DES: diethylstilbestrol
- DHEA: dihydroepiandrosterone
- DMPA: depo-medroxyprogesterone acetate or Depo-Provera®
- DUB: dysfunctional uterine bleeding
- DVT: deep venous thrombosis
- EPC: emergency postcoital contraception
- FSH: follicle-stimulating hormone
- GA: gestational age
- GIFT: gamete intrafallopian transfer
- GNRH: gonadotropin-releasing hormone
- GTN: gestational trophoblastic neoplasia
- GTD: gestational trophoblastic disease
- HERS: heart and estrogen/progestin replacement study
- HMG: human menopausal gonadotropin
- HPO: hypothalamic-pituitary-ovarian
- HRT: hormone replacement therapy
- HSV: herpes simplex virus
- ICSI: intracytoplasmic sperm injection
- IBD: inflammatory bowel disease
- ICSI: intracytoplasmic sperm injection
- IUD: intrauterine device
- IUI: intrauterine insemination
- IVF: in vitro fertilization
- JRA: juvenile rheumatoid arthritis
- LDLH: lactate dehydrogenase
- LEEP: loop electrosurgical excision procedure
- LH: luteinizing hormone
- LHRH: luteinizing hormone releasing hormone
- LMP: last menstrual period
- LL: lymph node
- LNM: last normal menstrual period
- LSI: low-grade squamous intraepithelial lesion
- LSV: lymphovascular space involvement
- MRKH: Mayer-Rokitansky-Küster-Hauser
- NN: natural killer
- OCP: oral contraceptive pill
- OD: oral glucose tolerance test
- PG: progestin
- PID: pelvic inflammatory disease
- PKD: polycystic kidney disease
- PMS: premenstrual syndrome
- PRP: rapid plasma reagin
- SCC: squamous cell carcinoma
- SERMs: selective estrogen receptor modifiers
- SES: socioeconomic class
- SHBG: sex hormone binding globulin
- SII: somatostatin
- SSRI: selective serotonin reuptake inhibitors
- STD: sexually transmitted disease
- TAH: total abdominal hysterectomy
- TET: tubal embryo transfer
- TH: total hysterectomy
- TOT: tension-free obturator tape
- TSH: thyroid stimulating hormone
- TTV: tension-free vaginal tape
- T2: transformation zone
- VDRL: venereal disease research laboratory

- W/D: withdrawal
- WHI: Women's Health Initiative
- ZIFT: zygote intrafallopian transfer

**Basic Anatomy Review**

**A. EXTERNAL GENITALIA (Figure 1)**
- Refers to collectively as the vulva
- Blood supply: internal pudendal artery
- Sensory innervation: pudendal nerve
- Lymphatic drainage: inguinal nodes

**B. VAGINA**
- Muscular canal extending from cervix to vulva, anterior to rectum and posterior to bladder
- Lined by rugated, stratified-squamous epithelium
- Upper vagina separated by cervix into anterior, posterior, and lateral fornices
- Blood supply: vaginal branch of internal pudendal artery with anastomoses from uterine, inferior vesical, and middle rectal arteries

**C. UTERUS**
- Thick walled, muscular organ between bladder and rectum, consisting of two major parts:
  - Uterine corpus
  - Blood supply: uterine artery (branch of internal iliac artery)
  - Cervix
  - Blood supply: cervical branch of uterine artery
- Supported by the pelvic diaphragm, the pelvic organs, and 4 paired sets of ligaments
- Round ligaments: travel from anterior surface of uterus, through broad ligaments, and inguinal canals then terminate in the labia majora
- Function: aneversion
- Blood supply: Sampson's artery (branch of uterine artery running through round ligament)
- Uterosacral ligaments: arise from sacral fascia and insert into posterior inferior uterus
- Function: mechanical support for uterus and contain autonomic nerve fibers
- Cardinal ligaments: extend from lateral pelvic wall and insert into lateral cervix and vagina
- Function: mechanical support, prevent prolapse
- Broad ligaments: pass from lateral pelvic wall to sides of uterus; contain fallopian tube, round ligament, ovarian ligament, nerves, vessels, and lymphatics
- Infundibulopelvic ligament: continuous tissue that connects ovary to pelvic wall
- Contains the ovarian artery, ovarian vein, ovarian plexus, and lymphatic vessels
- Position of the uterus:
  - Antverted (majority)
  - Retroverted

**Figure 1. Vulva and perineum**

**Figure 2. External genital organs**
D. FALLOPIAN TUBES
- 8-14 cm muscular tubes extending laterally from the uterus to ovary
- interstitial, isthmic, ampullary, and infundibular segments; terminates at fimbriae
- mesosalpinx: peritoneal fold that attaches fallopian tube to broad ligament
- blood supply: uterine and ovarian arteries

E. OVARIES
- consist of cortex with ova and medulla with blood supply
- supported by infundibulopelvic ligament (suspensory ligament of ovary)
- mesovarium: peritoneal fold that attaches ovary to broad ligament
- blood supply: ovarian arteries (branches off aorta), left ovarian vein (drains into left renal vein), right ovarian vein (drains into inferior vena cava)

Menstruation

Stages of Puberty
- see Pediatrics, P31
- adrenarche: increase in secretion of adrenal androgens; usually precedes gonadarche by 2 yr
- gonadarche: increased secretion of gonadal sex steroids; ~age 8
- thelarche: breast development
- pubarche: pubic and axillary hair development
- menarche: onset of menses, usually following peak height velocity and/or 2 yr following breast budding

Anteversion: forward-tilted uterus
Anteflexion: bending of uterus so the fundus is thrust forward
Retroversion: backward-tilted uterus
Retroflexion: bending of uterus so the fundus is thrust backward

Determination of uterine position by clinical exam:
- If cervix faces anteriorly (under the urethra and less easily accessible), i.e. toward vaginal orifice, more likely RETROVERTED UTERUS
- If cervix faces posteriorly (easily accessible), i.e. toward sacrum or rectum, more likely ANTEVERTED UTERUS
- If uterus palpable on bimanual exam, more likely ANTEVERTED UTERUS

“Water under the bridge”
The ureters run posterior to the uterine arteries

Stages of Puberty
“Boobs, Pubes, Grow, Flow”
Thelarche, Pubarche, Growth spurt, Menarche

Tanner Stage
Thelarche
I. None
II. Breast bud
III. Further enlargement of areola and breasts with no separation of contours
IV. 2nd mound of areola and papilla
V. Areola recessed to general contour of breast – adult

Pubarche
I. None
II. Downy hair along labia only
III. Darker/coarse hair extends over pubis
IV. Adult type covers smaller area, no thigh involvement
V. Adult hair in quantity and type; extends over thighs
### Characteristics
- Menarche: 10-15 yr
- Average: 12.2 yr
- Entire cycle: 28 ± 7 d with bleeding for 1-6 d
- 25-80 mL blood loss per cycle

### Estrogen
**ESTROGEN** is the main hormone in the follicular/proliferative phase and is stimulated by FSH. As the level increases it acts negatively on FSH. The majority of estrogen is secreted by the dominant follicle.

**Estrogen effects:**
- On the follicles in the ovaries: Reduces atresia
- On the endometrium: Proliferation of glandular and stromal tissue
- On all target tissues: Decreases E receptors

### Progesterone
**PROGESTERONE** is the main hormone in the luteal/secretory phase and is stimulated by LH. Increased progesterone acts negatively on LH and is secreted by the corpus luteum (remnant of dominant follicle).

**Progesterone effects:**
- On the endometrium:
  - Cessation of mitoses (stops building endometrium up)
- *"Organization"* of glands (initiates secretions from glands)
- Inhibits macrophages, interleukin-8, and enzymes from degrading endometrium
- On all target tissues:
  - Decrease E receptors (the "anti-estrogen" effect)
  - Decrease P receptors

---

*E = estrogen; FSH = follicle-stimulating hormone; GnRH = gonadotropin-releasing hormone; HPO = hypothalamic-pituitary-ovarian; LH = luteinizing hormone; P = progesterone*
Premenstrual Syndrome

- **synonyms:** "ovarian cycle syndrome," "menstrual molimina" (moodiness)

**Etiology**
- multifactorial: not completely understood; genetics likely play a role
- CNS-mediated neurotransmitter interactions with sex steroids (progesterone, estrogen, and testosterone)
- serotonergic dysregulation – currently most plausible theory

**Diagnostic Criteria for Premenstrual Syndrome**
- at least one affective and one somatic symptom during the 5 d before menses in each of the three prior menstrual cycles
  - affective: depression, angry outbursts, irritability, anxiety, confusion, social withdrawal
  - somatic: breast tenderness, abdominal bloating, headache, swelling of extremities
- symptoms relieved within 4 d of onset of menses
- symptoms present in the absence of any pharmacologic therapy, drug or alcohol use
- symptoms occur reproducibly during 2 cycles of prospective recording
- patient suffers from identifiable dysfunction in social or economic performance

**Treatment**
- goal: symptom relief
- psychological support
- diet/supplements
  - avoid sodium, simple sugars, caffeine, and alcohol
  - calcium (1,200-1,600 mg/d), magnesium (400-800 mg/d), vitamin E (400 IU/d), vitamin B₆
- medications
  - NSAIDs for discomfort, pain
  - spironolactone for fluid retention: used during luteal phase
  - SSRIs: used during luteal phase x 14 d or continuously
  - OCP: primarily beneficial for physical/somatic symptoms
  - danazol: an androgen that inhibits the pituitary-ovarian axis
  - GnRH agonists if PMS is severe and unresponsive to treatment (may use prior to considering definitive treatment with BSO)
- mind/body approaches
  - regular aerobic exercise
  - cognitive behavioral therapy
  - relaxation, light therapy biofeedback, and guided imagery
- herbal remedies (variable evidence)
  - evening primrose oil, black cohosh, St. John's wort, kava, ginkgo, agnus castus fruit extract
- BSO if symptoms severe

Premenstrual Dysphoric Disorder

**Definition**
- official diagnosis in the DSM-5
- described as a more severe form of PMS with specific diagnostic criteria
- treatment with SSRIs (first line), and Yaz® OCP (highly effective)
Differential Diagnoses of Common Presentations

Abnormal Uterine Bleeding

- see Disorders of Menstruation, GY11
- definition: change in frequency, duration, or amount of menstrual flow
- classified as
  - amenorrhea: absence of menstrual periods
  - hypomenorrhea: bleeding that is decreased in amount
  - oligomenorrhea: bleeding occurring at intervals >35 d
  - polymenorrhea: bleeding occurring at intervals <21 d
  - menorrhagia/hypermenorrhea: bleeding at regular intervals that is prolonged in duration (>7 d) or excessive in amount (>80 cc per menstrual cycle)
  - metrorrhagia: bleeding at irregular intervals, particularly between expected menstrual periods
  - menometrorrhagia: excessive bleeding at usual time of menstrual periods and at other irregular intervals
  - postmenopausal bleeding: any bleeding that presents >1 yr after menopause; must rule out endometrial cancer

Dysmenorrhea

- see Disorders of Menstruation, GY9
- primary/idiopathic
- secondary (acquired)
  - endometriosis
  - adenomyosis
  - uterine polyps
  - uterine anomalies (e.g. non-communicating uterine horn)
  - leiomyoma
  - intrauterine synechieae
  - ovarian cysts
  - cervical stenosis
  - imperforate hymen, transverse vaginal septum
  - pelvic inflammatory disease
  - IUD (copper)
  - foreign body

Vaginal Discharge/Pruritus

- see Gynecological Infections, GY23
- physiologic discharge and cervical mucus production
- non-physiologic
  - genital tract infection
  - vulvovaginitis: candidiasis, trichomoniasis, BV, polymicrobial superficial infection
  - chlamydia, gonorrhea
  - pyosalpinx, salpingitis
  - genital tract inflammation (non-infectious)
  - local: chemical irritants, douches, sprays, foreign body, trauma, atrophic vaginitis
  - desquamative inflammatory vaginitis, focal vulvitis
  - neoplasia: vulvar, vaginal, cervical, endometrial
  - systemic: toxic shock syndrome, Crohn's disease, collagen disease, dermatologic (e.g. lichen sclerosis)
  - IUD, OCP (secondary to progesterone)
Pelvic Pain

Figure 6. Approach to pelvic pain

Pelvic Mass

Figure 7. Differential diagnosis of pelvic mass
Dyspareunia

Figure 8. Approach to dyspareunia

Common Investigations and Procedures

Imaging

Ultrasound
- transabdominal or transvaginal U/S is the imaging modality of choice for pelvic structures
- transvaginal U/S provides better resolution of uterus and adnexal structures
  - detects early pregnancy if β-hCG ≥1,500 (β-hCG must be ≥6,500 for transabdominal U/S)
- may be used to identify pelvic pathology
  - identify ectopic pregnancy, intrauterine pregnancy
  - assess uterine, adnexal, cul-de-sac, ovarian masses (e.g. solid or cystic)
  - determine endometrial thickness, locate/characterize fibroids
  - monitor follicles during assisted reproduction
  - assess endometrial lining in postmenopausal women

Endometrial Biopsy
- performed in the office using an endometrial suction curette (pipelle) guided through the cervix to aspirate fragments of endometrium
  - pre-treatment with misoprostol (Cytotec) if nulliparous or postmenopausal
- more invasive procedure (D&C) may be done in the office or operating room ± hysteroscopy
- indications
  - AUB/PMB
  - cancer screening (e.g. following specific cervical cytology results (i.e. AGUS) or in high-risk women)

Hysterectomy

Indications
- uterine fibroids
- endometriosis, adenomyosis
- uterine prolapse
- pelvic pain
- AUB
- cancer (endometrium, ovaries, fallopian tubes, cervix)

Complications
- general anesthetic
- bleeding
- infection
- injury to other organs (ureter, bladder, rectum)
- loss of ovarian function (if ovaries removed, iatrogenic menopause)
Approaches
1. vaginal vs. abdominal
   • indications for vaginal approach: mobile uterus, uterine size <12 wk
   • advantages of vaginal approach: less pain, faster recovery time, allows for simultaneous repair of rectocele/cystocele/enterocele, improved aesthetics
2. open vs. laparoscopic-assisted
   • advantages of laparoscopy: less pain, faster recovery, improved aesthetics, shorter hospital stay
   • unless contraindicated or unavailable laparoscopic hysterectomy is the standard of care
3. robotic
   • similar advantages to laparoscopy
   • more dexterous

| Common etiology:                                                                   |                                                                                         |
| • Weight loss                                                                       |                                                                                         |
| • Excessive exercise                                                                |                                                                                         |
| • Systemic diseases                                                                 |                                                                                         |
| PCOS – hyperandrogenism                                                             |                                                                                         |
| Premature ovarian failure                                                            |                                                                                         |
| HP axis dysfunction                                                                 |                                                                                         |
| MRI hypothalamus, pituitary                                                         |                                                                                         |
| Measure other pituitary hormones                                                    |                                                                                         |
| Common etiology:                                                                   |                                                                                         |
| • Weight loss                                                                       |                                                                                         |
| • Excessive exercise                                                                |                                                                                         |
| • Systemic diseases                                                                 |                                                                                         |
| Functional hypothalamic amenorrhea is the most common cause of secondary amenorrhea |                                                                                         |

Investigations

- β-hCG, hormonal workup (TSH, prolactin, FSH, LH, androgens, estradiol)
- progesterone challenge to assess estrogen status
  - medroxyprogesterone acetate (Provera®) 10 mg PO OD for 10-14 d
  - any uterine bleed within 2-7 d after completion of Provera® is considered to be a positive test/withdrawal bleed
    - withdrawal bleed suggests presence of adequate estrogen to thicken the endometrium; thus withdrawal of progesterone results in bleeding
    - if no bleeding occurs, there may be inadequate estrogen (hypoestrogenism) or excessive androgens or progesterones (decidualization)
- karyotype: indicated if premature ovarian failure or absent puberty
- U/S to confirm normal anatomy, identify PCOS
### Treatment

### Abnormal Uterine Bleeding

**Abnormal Uterine Bleeding** change in frequency, duration, or amount of menstrual flow.

- **Gynecological**
  - Menorrhagia: Hormone imbalance, Fibroids/Leiomyomata, Uterine polyps, Adenomyosis, Copper IUD
  - Metrorrhagia/Menometrorrhagia: Trauma, sexual abuse, foreign body infection: endometritis, cervicitis, vaginitis, STD
  - Benign growths: uterine, cervical, vaginal
  - Pregnancy-related: Weight loss, excess exercise, stress
  - PCOS
  - DUB (diagnosis of exclusion)

- **Non-gynecological**
  - Endocrine: Hyper/hypothyroidism, Adrenal insufficiency
  - Insulin resistance (PCOS), Prolactinoma
  - Blood Dyscrasias: Coagulopathy (vWD), Platelet abnormalities (ITP), Leukemia
  - Hematologic malignancy
  - Renal Failure: Impaired estrogen excretion
  - Drugs: Anticoagulants, Danazol, OCP, HRT (breakthrough bleed), Spironolactone, Steroids, Chemotherapy, Neuroleptics
  - Hepatic Disease: Impaired estrogen metabolism

**Figure 10. Approach to abnormal uterine bleeding**

**Causal Conditions**
- pre-menarchal
  - trauma, sexual abuse
- pre-menopausal
  - ovulatory (see Table 5)
  - anovulatory (see Table 5)
- pregnancy-related
- post-menopausal
  - genital tract disease
    - atrophy
    - neoplasms
  - systemic disease
  - drugs
    - HRT
    - anti-coagulants

**Abnormal Uterine Bleeding** Determine if patient is hemodynamically stable prior to any other task.

**Hepatic Disease** Impaired estrogen metabolism (caused by factors).

**AUB in women >40 yr requires an endometrial biopsy to rule out cancer even if known to have fibroids**
Table 5. Comparison of Anovulatory and Ovulatory Abnormal Uterine Bleeding

<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Pathophysiology</td>
<td>Estrogen-dependent breakthrough bleeding: chronic estrogen production unopposed by adequate progesterone production → continued proliferation of the endometrium → thickened endometrium outgrows its blood supply → focal necrosis with partial shedding not uniformly → bleeding is usually irregular, prolonged, and heavy</td>
<td>Depends on underlying etiology</td>
</tr>
</tbody>
</table>

**Investigations**

- vitals ± orthostatic vitals
- CBC, serum ferritin
- β-hCG to rule out pregnancy
- TSH, free T₁
- coagulation profile (especially in adolescents): rule out von Willebrand’s disease
- prolactin if amenorrheic
- FSH, LH
- serum androgens (especially free testosterone)
- day 21 (luteal phase) progesterone to confirm ovulation
- Pap test
- pelvic U/S: detect polyps, fibroids, measure endometrial thickness (postmenopausal)
- SHG: very sensitive for intruterine pathology (polyps, submucous fibroids)
- HSG
- endometrial biopsy: consider biopsy in women >40 yr
  - must do endometrial biopsy in all women presenting with postmenopausal bleeding to exclude endometrial cancer
- D&C: not for treatment; diagnosis only (usually with hysteroscopy)

**Treatment**

- resuscitate patient if hemodynamically unstable
- treat underlying disorders
  - if anatomic lesions and systemic disease have been ruled out, consider DUB
  - medical
    - mild DUB
      - NSAIDs
      - anti-fibrinolytic (e.g. Cyklokapron*) at time of menses
      - combined OCP
      - progestins (“Provera”) on first 10-14 d of each mo or every 3 mo if oligomenorrheic
      - Mirena* IUD
      - danazol
    - acute, severe DUB
      - replace fluid losses, consider admission
        - a) estrogen (Premarin*) 25 mg IV q4h x 24 h with dimenhydrinate 50 mg IV/PO q4h or anti-fibrinolytic (e.g. Cyklokapron*) 10 mg/kg IV q8h
        - b) any OCP with minimum 50 µg estradiol 1 tab PO q4h x 24 h with dimenhydrinate 50 mg IV/PO q4h
          - taper to 1 tab tid x 2 d → bid x 2 d → OD
          - after (a) or (b), maintain patient on monophasic OCP for next several months or consider alternative medical treatment
      - clomiphene citrate
        - consider in patients who are anovulatory and who wish to get pregnant
      - surgical
        - endometrial ablation; consider pretreatment with danazol or GnRH agonists
          - if finished childbearing
          - repeat procedure may be required if symptom reoccur especially if <40 yr
        - hysterectomy: definitive treatment

**Dysfunctional Uterine Bleeding**

Abnormal bleeding not attributable to organic (anatomic/systemic) disease; DUB is a diagnosis of exclusion; anovulatory AUB often used synonymously with DUB.
**Dysmenorrhea**

**Etiology**
- see Differential Diagnoses of Common Presentations, GY6

**Table 6. Comparison of Primary and Secondary Dysmenorrhea**

<table>
<thead>
<tr>
<th>Features</th>
<th>Primary Dysmenorrhea</th>
<th>Secondary Dysmenorrhea</th>
</tr>
</thead>
<tbody>
<tr>
<td>Menstrual pain in absence of organic disease Begins 6 mo-2 yr after menarche (once ovulatory cycles established)</td>
<td>Menstrual pain due to organic disease Usually begins in women who are in their 20s, worsens with age May improve temporarily after childbirth</td>
<td></td>
</tr>
<tr>
<td>Signs and Symptoms</td>
<td>Colicky pain in abdomen, radiating to the lower back, labia, and inner thighs beginning hours before onset of bleeding and persisting for hours or days (48-72 h) Associated symptoms: N/V, altered bowel habits, headaches, fatigue (prostaglandin-associated)</td>
<td>Associated dyspareunia, abnormal bleeding, infertility</td>
</tr>
<tr>
<td>Diagnosis</td>
<td>Associated dyspareunia, abnormal bleeding, infertility Rule out underlying pelvic pathology and confirm cyclic nature of pain</td>
<td>Bimanual exam: uterine or adnexal tenderness, fixed uterine retroflexion, uterosacral nodularity, pelvic mass, or enlarged irregular uterus (findings are rare in women &lt;20 yr) U/S, laparoscopy and hysteroscopy may be necessary to establish the diagnosis Screening for infections (vaginal and cervical cultures) and Papanicolaou smear may be required</td>
</tr>
<tr>
<td>Treatment</td>
<td>PG synthetase inhibitors (e.g. Anaprox®) should be started before onset of pain OCP: suppress ovulation/reduce menstrual flow</td>
<td>Treat underlying cause</td>
</tr>
</tbody>
</table>

**Endometriosis**

**Etiology**
- not fully understood
- proposed mechanisms (combination likely involved)
  - retrograde menstruation (Sampson’s theory)
    - seeding of endometrial cells by transtubal regurgitation during menstruation
    - endometrial cells most often found in dependent sites of the pelvis
  - immunologic theory: altered immunity may limit clearance of transplanted endometrial cells from pelvic cavity (may be due to decreased NK cell activity)
  - metaplasia of coelomic epithelium
    - undefined endogenous biochemical factor may induce undifferentiated peritoneal cells to develop into endometrial tissue
  - extrapelvic disease may be due to aberrant vascular or lymphatic dissemination of cells
    - e.g. ovarian endometriosis may be due to direct lymphatic flow from uterus to ovaries

**Epidemiology**
- incidence: 15-30% of pre-menopausal women
- mean age at presentation: 25-30 yr
- regresses after menopause

**Risk Factors**
- family history (7-10x increased risk if affected 1st degree relative)
- obstructive anomalies of the genital tract (earlier onset) – resolve with treatment of anomaly
- nulliparity
- age >25 yr

**Sites of Occurrence**
- ovaries: 60% patients have ovarian involvement
- broad ligament, vesicoperitoneal fold
- peritoneal surface of the cul-de-sac, uterosacral ligaments
- rectosigmoid colon, appendix
- rarely may occur in sites outside abdomen/pelvis, including lungs
Clinical Features
• may be asymptomatic
• history
  • menstrual symptoms
  • cyclic symptoms due to growth and bleeding of ectopic endometrium, usually precede menses (24-48 h) and continue throughout and after flow
  • secondary dysmenorrhea
  • sacral backache with menses
  • pain may eventually become chronic, worsening perimenstrually
  • premenstrual and postmenstrual spotting
  • deep dyspareunia
• infertility
  • 30-40% of patients with endometriosis will be infertile
  • 15-30% of those who are infertile will have endometriosis
• bowel and bladder symptoms
  • frequency, dysuria, hematuria
  • diarrhea, constipation, hematochezia, dyschezia
• physical
  • tender nodularity of uterine ligaments and cul-de-sac felt on rectovaginal exam
  • fixed retroversion of uterus
  • firm, fixed adnexal mass (endometrioma)
  • physical findings not present in adolescent population

Investigations
• definitive diagnosis requires
  • direct visualization of lesions typical of endometriosis at laparoscopy
  • biopsy and histologic exam of specimens (2 or more of: endometrial epithelium, glands, stroma, hemosiderin-laden macrophages)
  • laparoscopy
  • mulberry spots: dark blue or brownish-black implants on the uterosacral ligaments, cul-de-sac, or anywhere in the pelvis
  • endometrioma: “chocolate” cysts on the ovaries
  • “powder-burn” lesions on the peritoneal surface
  • early white lesions and clear blebs
  • peritoneal “pockets”
• CA-125
• may be elevated in patients with endometriosis

Treatment
• depends on certainty of the diagnosis, severity of symptoms, extent of disease, desire for future fertility, and impact to GI/GU systems (e.g. intestinal obstruction)
• medical
  • NSAIDs (e.g. naproxen sodium – Anaprox®)
  • pseudopregnancy
    • cyclic/continuous estrogen-progesterin (OCP)
    • medroxyprogesterone (Depo-Provera®)
  • dienogest (Natazia®)
  • pseudomenopause
  • 2nd line: only short-term (<6 mo) due to osteoporotic potential with prolonged use, unless combined with add-back therapy (e.g. estrogen/progesterone or SERM); if long-term use required, add-back estrogen+progesterone
  • danazol (Danocrine®): weak androgen
    – side effects: weight gain, fluid retention, acne, hirsutism, voice change
  • leuprolide (Lupron®): GnRH agonist (suppresses pituitary)
    – side effects: hot flashes, vaginal dryness, reduced libido
    – can use ≥12 mo with add-back progestin or estrogen
• surgical
  • conservative laparoscopy using laser, electrocautery ± laparotomy
  • ablation/resection of implants, lysis of adhesions, ovarian cystectomy of endometriomas
  • definitive: bilateral salpingo-oophorectomy ± hysterectomy
  • ± follow-up with medical treatment for pain control not shown to impact on preservation of fertility
  • best time to become pregnant is immediately after conservative surgery

There may be little correlation between the extent of endometriosis and symptomatology

Classic Triad of Endometriosis
• Dysmenorrhea
  • Dyspareunia (cul-de-sac, uterosacral ligament)
• Dyschezia (uterosacral ligament, cul-de-sac, recto-sigmoid attachment)

A sharp, firm, and exquisitely tender “bark” on the uterosacral ligament is a classic feature of endometriosis

Laparoscopic Surgery for Endometriosis
Cochrane Databse of Systematic Reviews 2014:CD011031

Purpose: To assess the effectiveness and safety of laparoscopic surgery for the treatment of painful symptoms and infertility associated with endometriosis.

Selection Criteria: RCTs in which effectiveness and safety of laparoscopic surgery was compared with any other laparoscopic or robotic intervention, holistic or medical treatment, or diagnostic laparoscopy only.

Results: 10 RCTs, 973 participants. Laparoscopic surgery was associated with increased overall pain compared with diagnostic laparoscopy at 6 and 12 mo (OR 5.6, 95% CI 3.31-9.31; OR 10.00, 95% CI 3.21-31.17). Laparoscopic surgery was also associated with increased pregnancy rate compared with diagnostic laparoscopy (OR 1.94, 95% CI 1.20-3.16) and increased pregnancy rate (OR 1.94, 95% CI 1.29-2.80). Compared to diagnostic laparoscopy plus medical therapy (GnRHa plus add-back therapy), laparoscopic ablation resulted in a greater number of participants reporting no pain at 12 mo (OR 5.63, 95% CI 1.18-26.85) although there was no difference in overall/pain relief at 12 mo comparing laparoscopic ablation to laparoscopic excision.

Conclusions: Moderate quality evidence suggests that laparoscopic surgery to treat mild and moderate endometriosis reduces overall pain and increases live birth and ongoing pregnancy rates. There was insufficient evidence on adverse events to allow any conclusions regarding safety.

Endometriosis is classified according to a scoring system standardized by the American Society for Reproductive Medicine; score is based on location and extent of disease

Recurrent Rates
Medical therapy: 30-50%
Conservative surgery: 14-40%
Adenomyosis

- synonym: "endometriosis interna" (uterine wall may be diffusely involved)

Epidemiology
- 15% of females >35 yr old; found in 20-40% of hysterectomy specimens
- mean age at presentation: 40-50 yr old (older age group than seen in endometriosis)
- adenomyosis is a common histologic finding in asymptomatic patients

Clinical Features
- often asymptomatic
- menorrhagia, secondary dysmenorrhea, pelvic discomfort
- dyspareunia, dyschezia
- uterus symmetrically bulky, usually <14 cm, mobility not restricted, no associated adnexal pathology
- Halban sign: tender, softened uterus on premenstrual bimanual exam

Investigations
- clinical diagnosis
- U/S or MRI can be helpful
- endometrial sampling to rule out other pathology

Treatment
- iron supplements as necessary
- analgesics, NSAIDs
- OCP, medroxyprogesterone (Depo-Provera°)
- low dose danazol 100-200 mg PO OD (trial x 4 mo)
- GnRH agonists (e.g. leuprolide)
- definitive: hysterectomy (no conservative surgical treatment)

Leiomyomata (Fibroids)

Epidemiology
- diagnosed in approximately 40-50% of pre-menopausal women >35 yr
- more common in African Americans, where they are also larger and occur at earlier age
- common indication for major surgery in females
- minimal malignant potential (1:1,000)
- typically regress after menopause; enlarging fibroids in a postmenopausal woman should prompt consideration of malignancy
  - 50% of leiomyosarcomas originate from within fibroids

Pathogenesis
- estrogen stimulates monoclonal smooth muscle proliferation
- progesterone stimulates production of proteins that inhibit apoptosis
- degenerative changes (occur when tumor outgrows blood supply)
  - hyaline degeneration (most common degenerative change)
  - cystic degeneration (from breakdown of hyaline)
  - red/carneous degeneration (hemorrhage into tumor, may occur in pregnancy)
  - fatty degeneration
  - calcification
  - sarcomatous degeneration (rare)
  - parasitic myoma: tumor becomes attached to another organ (typically omentum or small bowel mesentery), develops new blood supply and loses connection to uterus

Clinical Features
- majority asymptomatic (60%), often discovered as incidental finding on pelvic exam or U/S
- abnormal uterine bleeding (30%): dysmenorrhea, menorrhagia
- pressure/bulk symptoms (20-50%)
  - pelvic pressure/heaviness
  - increased abdominal girth
  - urinary frequency and urgency
  - acute urinary retention (extremely rare but surgical emergency!)
  - constipation, bloating (rare)
- acute pelvic pain
  - fibroid degeneration
  - dyspareunia, dyschezia
  - fibroid torsion (pedunculated subserosal)

Adenomyosis

- Extension of areas of endometrial glands and stroma into the myometrium

Final diagnosis of adenomyosis is based on pathologic findings, but predictably identified on MRI

Leiomyomata/Fibroids

- Benign smooth muscle tumor of the uterus (most common gynecological tumor)
- Submucosal leiomyomata are most symptomatic (bleeding, infertility)
- AUB in women >40 yr requires an endometrial biopsy to rule out cancer even if known to have fibroids

Figure 11. Possible anatomic locations of uterine leiomyomata
• infertility, recurrent pregnancy loss
• pregnancy complications (potential enlargement and increased pain, obstructed labor, difficult C-section)

**Investigations**
• bimanual exam: uterus asymmetrically enlarged, usually mobile
• CBC: anemia
• U/S: to confirm diagnosis and assess location of fibroids
• sonohysterogram: useful for differentiating endometrial polyps from submucosal fibroids, or if intracavitary growth
• endometrial biopsy to rule out uterine cancer for abnormal uterine bleeding (especially if age >40 yr)
• occasionally MRI is used for pre-operative planning (e.g. before myomectomy)

**Treatment**
• only if symptomatic, rapidly enlarging, menorrhagia, menometrorrhagia, intracavitary
• treat anemia if present
• only if symptomatic, rapidly enlarging, menorrhagia, menometrorrhagia
• occasionally MRI is used for pre-operative planning (e.g. before myomectomy)
• U/S: to confirm diagnosis and assess location of fibroids
• CBC: anemia
• bimanual exam: uterus asymmetrically enlarged, usually mobile

*Contraception*

</table>

Effectiveness: percentage of women reporting no pregnancy after 1 yr of use.

Hormonal Methods

Combined Oral Contraceptive Pills
- most contain low dose ethinyl estradiol (20-35 µg) plus progestin (norethindrone, norgestrel, levonorgestrel, desogestrel, norgestimate, drospirenone)
- failure rate (0.3% to 8%) depending on compliance
- monophasic or triphasic formulations (varying amount of progestin throughout cycle)

Transdermal (Ortho Evra®)
- continuous release of 6 mg norelgestromin and 0.60 mg ethinyl estradiol into bloodstream
- applied to lower abdomen, back, upper arm, buttocks, NOT breast
- worn for 3 consecutive wk (changed every wk) with 1 wk off to allow for menstruation
- as effective as OCP in preventing pregnancy (>99% with perfect use)
- may be less effective in women >90 kg
- may not be covered by drug plans

Contraceptive Ring (Nuva Ring®)
- thin flexible plastic ring; releases etonogestrel 120 µg/d and estradiol 15 µg/d
- works for 3 wk then removed for 1 wk to allow for menstruation
- as effective as OCP in preventing pregnancy (98%)
- avoids first pass effect
- side effects: vaginal infections/irritation, vaginal discharge
- may have better cycle control; i.e. decreased breakthrough bleeding

Starting Hormonal Contraceptives
- thorough history and physical exam, including blood pressure and breast exam
- follow-up visit 6 wk after hormonal contraceptives prescribed
- pelvic exam not required as STD screening can be done by urine and pap smear screening does not start until >21 yr

Rates of Venous Thromboembolism (VTE: DVT and PE) expressed in women/yr
- Non-users of reproductive age: 4-6/10,000
- OCP users*: 9-10/10,000
- Pregnancy: 28/10,000
- Immediate post-partum: 300-400/10,000

*Risk is highest in the first months of use and in medication switch.

Effect of Ethinyl Estradiol Dose
- ALL OCPs with ~35 µg ethinyl estradiol carry a lower risk of VTE compared with oral contraceptives with 50 µg.

Effect of Progestin Type
- Drospirenone: third generation progestin, e.g. “foostrin®” and “pop®”
- Levonorgestrel: second generation progestin, e.g. “Alesse®”

Two high quality research studies found comparable VTE rates with drospirenone-containing OCPs and other approved products.
1. Dinger et al., Contraception 2007;76:244-254
2. Seeger et al., Obstet Gynecol 2007;110:587-593

Two reports with significant methodological flaws found increased VTE risk. Results and conclusions may have been distorted by residual confounding.
1. Lidegaard et al., BMJ 2009;339:b2920
2. Van Hylckama Vlieg et al., BMJ 2009;339:b2921

Conclusion
- Occurrence of serious risks, such as VTE, is rare with all contemporary OCPs.
- Individualized risk assessment is mandatory.
- For most healthy women of reproductive age, the benefits of OCPs will outweigh the risks.

Risk of Non-Fatal Venous Thromboembolism in Women Using Oral Contraceptives Containing Drospirenone Compared with Women Using Oral Contraceptives Containing Levonorgestrel: A Case-Control Study Using United States Claims Data
BMJ 2011;342:d2325

Study: Nested case-control cohort study.
- Patients: Women aged 15-44 yr receiving oral contraceptives.
- Intervention: Drospirenone-containing contraceptive vs. levonorgestrel-containing contraceptive.
- Outcome: Non-fatal venous thromboembolism.
- Results: Women receiving drospirenone-containing oral contraceptives were two times as likely to develop non-fatal VTE compared to women receiving levonorgestrel-containing contraceptives (age adjusted incidence rate ratio was 2.8).

</tbody>
</table>

Absolute

- Known/suspected pregnancy
- Undiagnosed abnormal vaginal bleeding
- Prior thromboembolic events, thromboembolic disorders (Factor V Leiden mutation; protein C or S, or antithrombin III deficiency), active thrombophlebitis
- Cerebrovascular or coronary artery disease
- Estrogen-dependent tumors (breast, uterus)
- Impaired liver function associated with acute liver disease
- Congenital hyperlipidemia
- Smoker age >35 yr
- Migraines with focal neurological symptoms (excluding aura)
- Uncontrolled HTN

Relative

- Migraines (non-focal with aura <1 h)
- DM complicated by vascular disease
- SLE
- Controlled HTN
- Hyperlipidemia
- Sickle cell anemia
- Gallbladder disease

Drug Interactions/Risks

- Rifampin, phenobarbital, phenytoin, and primidone can decrease efficacy, requiring use of back-up method
- No evidence of fetal abnormalities if conceived on OCP
- No evidence that OCP is harmful to nursing infant but may decrease milk production; not recommended until 6 wk postpartum, ideally until 3 mo postpartum

 irr Regular breakthrough bleeding often occurs in the first few months after starting OCP, usually resolves after three cycles

 irr Missed Combined OCPs

- Miss 1 pill in <24 h
  - Take 1 pill ASAP and the next pill at the usual time
- Miss >1 pill in a row in first wk
  - Take 1 pill ASAP and continue taking one pill daily until the end of the pack
  - Use back-up contraception for 7 d; EPC may be necessary
- Miss <3 pills in 2nd or 3rd wk of cycle
  - Take 1 pill ASAP and continue taking one pill daily until the end of the pack
  - Do not take placebo (21-d packs) or do not take a hormone free interval (21-d packs)
  - Start the next pack immediately after finishing the previous one
  - No need for back-up contraception
- Miss ≥3 pills during the 2nd or 3rd wk
  - Take 1 pill ASAP and continue taking one pill daily until the end of the pack
  - Do not take placebo (21-d packs) or do not take a hormone free interval (21-d packs)
  - Start the next pack immediately after finishing the previous one
  - Use back-up contraception for 7 d; EPC may be necessary

Nexplanon is the second generation model which contains barium sulfate to make it radio-opaque so its position can be visualized by x-ray if unable to palpate the rod to remove it.

Depo-Provera®
• injectable depot medroxyprogesterone acetate
dose 150 mg IM q12-14wk (convenient dosing)
initiate within 5 d of beginning of normal menses, immediately postpartum in breastfeeding and non-breastfeeding women
irregular spotting progresses to complete amenorrhea in 70% of women (after 1-2 yr of use)
highly effective 99%; failure rate 0.3%
side effect: decreased bone density (may be reversible)
disadvantage: restoration of fertility may take up to 1-2 yr

Nexplanon/Implanon®
• subdermal contraceptive rod
contains 68 mg of etonogestrel, released at a rate of 25-30 µg per d
inserted subdermally into the inner side of the non-dominant upper arm
highly effective 99%; failure rate 0.3%
side effect: decreased bone density (may be reversible)
disadvantage: restoration of fertility may take up to 1-2 yr

Disadvantage: restoration of fertility may take up to 1-2 yr

Absolute
• Both Copper and Progestrone IUD
Known or suspected pregnancy
Undiagnosed genital tract bleeding
Acute or chronic PID
Lifestyle risk for STDs*
Copper IUD:
Known allergy to copper
Wilson’s disease
Relative
• Both Copper and Progestrone IUD
Malignant heart disease
Past history of PID or ectopic pregnancy
Presence of prosthesis
Abnormalities of uterine cavity, intracavitary fibroids
Cervical stenosis
Immune suppressed individuals (e.g. HIV)
Copper IUD: severe dysmenorrhea or menorrhagia

Cervical swabs for gonorrhea and chlamydia should be done prior to IUD insertion.

Depot Medroxyprogesterone Acetate and Bone Effects
ACOG Committee Opinion 415, 2006
Obstet Gynecol 2006;108:727-730
• The effect of DMPA on BMD should neither prevent practitioners from prescribing DMPA nor limit its use to 2 consecutive yr.
• The greatest loss of BMD occurs in the first 1-2 yr of DMPA use.
• Contraceptive implants and intrauterine devices that do not affect BMD should be considered as first-line for adolescents.
• Inform patients about benefits and the potential risks of DMPA, and encourage daily exercise, calcium and vitamin D intake.
• Routine BMD monitoring is not recommended for DMPA users.

Steroidal Contraceptives and Bone Fractures in Women: Evidence from Observational Studies
Cochrane DB Syst Rev 2003;3:CD004695
Background: Steroidal contraceptives have been associated with effects on bone mineral density (BMD) in women.
Study: Systematic review of observational studies of comparisons of hormonal contraceptive with nonhormonal contraceptive, no contraceptive, or other hormonal contraceptive on bone density.
Results: 7 case-control and 7 cohort studies were included.
• One study reported increased fracture risk for depot medroxypregesterone acetate (DMPA) ever-use (OR 1.44), >4 yr use (OR 2.16).
• One study reported decreased fracture risk for continuous use (OR 0.79) and longer use of hormonal IUD.

Continuous or Extended Cycle vs. Cyclic Use of Combined Oral Contraceptives for Contraception
Cochrane DB Syst Rev 2005;3:CD004869
Background: The efficacy and side effects of cyclic administration vs. extended use (longer periods of active pills and/or shorter periods placebo) or continuous use (uninterrupted active pill administration) of combined oral contraceptives (COC) are unclear.
Study: Systematic review of randomized clinical trials comparing continuous or extended vs. cyclic COC administration.
Findings: Eight RCTs met inclusion criteria.
• No difference in efficacy of pregnancy prevention.
• No difference in compliance with dosing schedules.
• Extended cycle use lowered prevalence of menstrual symptoms (e.g. headaches, pain, fatigue).
Emergency Postcoital Contraception

</tbody>
</table>

Follow-up
- 3-4 wk post treatment to confirm efficacy (confirmed by spontaneous menses or pregnancy test)
- contraception counseling

---

**Infertility**

### Epidemiology
- 10-15% of couples
- must investigate both members of the couple

### Female Factors

**Etiology**
- ovulatory dysfunction (15-20%)
  - hypothalamic (hypothalamic amenorrhea)
  - pituitary (prolactinoma, hypopituitarism)
  - ovarian
    - PCOS
    - premature ovarian failure
    - luteal phase defect (poor follicle production, premature corpus luteum failure, failed uterine lining response to progesterone, poorly understood
    - systemic diseases (thyroid, Cushing’s syndrome, renal/hepatic failure)
    - congenital (Turner’s syndrome, gonadal dysgenesis or gonadotropin deficiency)
    - stress, poor nutrition, excessive exercise (even with presence of menstruation)
  - outflow tract abnormality (15-20%)
    - tubal factors (20-30%)
    - PID
    - adhesions (previous surgery, peritonitis, endometriosis)
    - ligament/occlusion (e.g. previous ectopic pregnancy)
  - uterine factors (<5%)
    - congenital anomalies, bicornuate uterus, septate uterus, prenatal DES exposure
    - intruterine adhesions (e.g. Asherman’s syndrome)
    - infection (endometritis, pelvic TB)
    - fibroids/polyps (particularly intruterine)
    - endometrial ablation
  - cervical factors (5%)
    - hostile or acidic cervical mucus
    - anti-sperm antibodies
    - structural defects (cone biopsies, laser or cryotherapy)
- Requirements for Conception
  - Ovary
  - Tube
  - Cervix
  - Endometrium
  - Sperm

Infertility: inability to conceive or carry to term a pregnancy after 1 yr of regular, unprotected intercourse

Primary infertility: infertility in the context of no prior pregnancies

Secondary infertility: infertility in the context of a prior conception

Generally, 75% of couples achieve pregnancy within 6 mo, 85% within 1 yr, 90% within 2 yr
endometriosis (15-30%)
multiple factors (30%), see GY22
unknown factors (10-15%)

Investigations
ovulatory
- day 3: FSH, LH, TSH, prolactin ± DHEA, free testosterone (if hirsute)
- day 21-23: serum progesterone to confirm ovulation
- initiate basal body temperature monitoring (biphasic pattern)
- postcoital test: evaluate mucus for clarity, pH, spinnbarkeit/fibrosity (rarely done)
tubal factors
- HSG (can be therapeutic – opens fallopian tube)
- SHG (can be therapeutic – opens fallopian tube)
laparoscopy with dye insufflation (or tubal dye test)
peritoneal/uterine factors
- HSG/SHG, hysteroscopy
other
- karyotype

Treatment
education: timing of intercourse in relation to ovulation (from 2 d prior to 2 d following presumed ovulation), every other day
medical
- ovulation induction
  - clomiphene citrate (Clomid®): estrogen antagonist that causes a perceived decreased estrogen state, resulting in increased pituitary gonadotropins; causes increased FSH and LH, leading to ovulation induction (works much better if anovulatory)
  - human menopausal gonadotropin – FSH and LH extracted from urine of postmenopausal women
  - followed by β-hCG for stimulation of ovum release
  - may add
    - bromocriptine (dopamine agonist) if elevated prolactin
    - dexamethasone for hyperandrogenism (adult onset congenital adrenal hyperplasia)
    - metformin (for PCOS)
    - luteal phase progesterone supplementation for luteal phase defect (mechanism not completely understood)
  - ASA (81 mg PO OD) for women with a history of recurrent spontaneous abortions (for antiphospholipid antibody syndrome)
surgical/procedural
- tubuloplasty
- lysis of adhesions
artificial insemination: intracervical insemination (ICI), intrauterine insemination (IUI), intrauterine tuboperitoneal insemination (IUTPI), intratubal insemination (ITI)
sperm washing
IVF (in vitro fertilization)
IFT (intratubal transfer)
GIFT (gamete intrafallopian transfer): immediate transfer with sperm after oocyte retrieval
ZIFT (zygote intrafallopian transfer): transfer after 24 h culture of oocyte and sperm
TET (tubal embryo transfer): transfer after >24 h culture
ICSI (intracytoplasmic sperm injection)
IVM (in vitro maturation)
± oocyte or sperm donors
± pre-genetic screening for single gene defects in karyotype of zygote

Male Factors
see Urology, U33

Etiology
- varicocele (>40%)
- idiopathic (>20%)
- obstruction (~15%)
- cryptorchidism (~8%)
- immunologic (~3%)

Investigations
- semen analysis and culture
- postcoital (Huhner) test: rarely done

When Should Investigations Begin?
- <35 yr: after 1 yr of regular unprotected intercourse
- 35-40 yr: after >6 mo
- >40 yr: immediately
- Earlier if:
  - History of PID
  - History of infertility in previous relationship
  - Prior pelvic surgery
  - Chemotherapy/radiation in either partner
  - Recurrent pregnancy loss
  - Moderate-severe endometriosis

Controversial and Evolving Ethical Issues
Infertility demands non-judgmental discussion
Ethical issues surrounding therapeutic donor insemination in same sex couples, surrogacy, donor gametes, and other advanced reproductive technologies are still evolving and remain controversial
If the doctor finds that certain treatment options lie outside of their moral boundaries, the infertile couple should be referred to another physician

Normal Semen Analysis (WHO lower reference limits)
- Must be obtained after 2-7 d of abstinence
- Volume 1.5 cc
- Count 15 million/cc
- Vitality 58% live
- Motility 32% progressive, 40% total (progressive + non-progressive)
- Morphology 4.0% normal
Polycystic Ovarian Syndrome

- also called chronic ovarian androgenism

Etiology

- laboratory
  - prolactin, 17-hydroxyprogesterone, free testosterone, DHEA-S, TSH, free T₄, androstenedione, SHBG
  - LH:FSH >2:1; LH is chronically high with FSH mid-range or low (low sensitivity and specificity)
  - increased DHEA-S, androstenedione and free testosterone (most sensitive), decreased SHBG

- transvaginal or transabdominal U/S: polycystic-appearing ovaries ("string of pearls" – 12 or more small follicles 2-9 mm, or increased ovarian volume)

- tests for insulin resistance or glucose tolerance
  - fasting glucose:insulin ratio <4.5 is consistent with insulin resistance (U.S. units)
  - 75 g OGTT yearly (particularly if obese)

- laparoscopy
  - not required for diagnosis
  - most common to see white, smooth, sclerotic ovaries with a thick capsule; multiple follicular cysts in various stages of atresia; hyperplastic theca and stroma

- rule out other causes of abnormal bleeding

Treatment

- cycle control
  - lifestyle modification (decrease BMI, increase exercise) to decrease peripheral estrone formation
  - OCP monthly or cyclic Provera® to prevent endometrial hyperplasia due to unopposed estrogen
  - oral hypoglycemic (e.g. metformin) if type 2 diabetic or if trying to become pregnant
  - tranexamic acid (Cyklokapron®) for menorrhagia only

- infertility
  - medical induction of ovulation: clomiphene citrate, human menopausal gonadotropins (HMG [Pergonal®]), LHRI, recombinant FSH, and metformin
  - metformin may be used alone or in conjunction with clomiphene citrate for ovulation induction
  - ovarian drilling (perforate the stroma), wedge resection of the ovary
  - bromocriptine (if hyperprolactinemia)

- hirsutism
  - any OCP can be used
  - Androcur® (cyproterone acetate): antiandrogenic
  - Yasmin® (drospirenone and ethinyl estradiol): spironolactone analogue (inhibits steroid receptors)
  - mechanical removal of hair
  - finasteride (5-a reductase inhibitor)
  - flutamide (androgen reuptake inhibitor)
  - spironolactone: androgen receptor inhibitor

- hyperlipidemia
- hyperprolactinemia
- hypothyroidism

Use of Metformin in Polycystic Ovary Syndrome. A Meta-Analysis

Oblast Gynecol 2008;11(4):959-68.
Study: This meta-analysis of 17 RCTs assessed the efficacy of metformin or metformin in combination with clomiphene citrate in women with PCOS who were seeking pregnancy.

Main Outcomes: Ovulation, pregnancy, and live birth. Patients: 1,639 patients with PCOS were seeking pregnancy. Results: Compared to placebo, metformin increased the odds of ovulation (OR 2.94, 95% CI 1.43-6.02). However, when used alone, metformin did not significantly increase the odds of achieving pregnancy (OR 1.58, 95% CI 0.74-3.33). When compared to clomiphene alone, the combination of metformin and clomiphene increased the likelihood of ovulation (OR 4.39, 95% CI 1.84-9.98) and pregnancy (OR 2.67, 95% CI 1.45-4.94). The effect of combination therapy was most prominent in clomiphene-resistant and obese women with PCOS. Furthermore, the combination therapy had a higher likelihood of having a live birth compared to clomiphene alone, but this did not reach significance (OR 1.74, 95% CI 0.79-3.86).

Conclusions: Metformin increases the likelihood of ovulation. When used together with clomiphene, metformin increases the likelihood of both ovulation and pregnancy, especially in clomiphene-resistant and obese women.
Gynecological Discharge

- clear, white, flocculent, odorless discharge; pH 3.8-4.2
- smear contains epithelial cells, Lactobacilli
- increases with increased estrogen states: pregnancy, OCP, mid-cycle, PCOS, or premenarchal
- if increased in perimenopausal/postmenopausal woman, consider investigation for other effects of excess estrogen (e.g. endometrial cancer)

Vulvovaginitis

PREPUBERTAL VULVOVAGINITIS

- clinical features
  - irritation, pruritus
  - discharge
  - vulvar erythema
  - vaginal bleeding (specifically due to Group A Streptococci and Shigella)
- differential diagnosis
  - non-specific vulvovaginitis (25-75%)
  - infections (respiratory, enteric, systemic, sexually acquired)
  - foreign body (toilet paper most common)
  - Candida (if using diapers)
  - pinworms
  - polyps, tumor (ovarian malignancy)
  - vulvar skin disease (lichen sclerosis, condyloma acuminata)
  - trauma (accidental straddle injury, sexual abuse)
  - psychosomatic vaginal complaints (specific to vaginal discharge)
  - endocrine abnormalities (specific to vaginal bleeding)
  - blood dyscrasia (specific to vaginal bleeding)
- etiology
  - infectious
    - poor hygiene, proximity of vagina to anus
    - recent infection (respiratory, enteric, systemic)
    - STD: investigate sexual abuse
  - nonspecific
    - lack of protective hair and labial fat pads
    - lack of estrogenization
    - susceptible to chemicals, soaps (bubble baths), medications, and clothing
    - enuresis
- investigations
  - vaginal swab for culture (specifically state that it is a pre-pubertal specimen), pH, wet-mount, and KOH smear in adults only
- treatment
  - enhanced hygiene and local measures (handwashing, white cotton underwear, no nylon tights, no tight fitting clothes, no sleeper pajamas, sitz baths, avoid bubble baths, use mild detergent, eliminate fabric softener, avoid prolonged exposure to wet bathing suits, urination with legs spread apart)
  - A&D® dermatological ointment (vitamin A/D) to protect vulvar skin
  - infectious: treat with antibiotics for organism identified

Table 13. Other Common Causes of Vulvovaginitis in Prepubertal Girls

# POSTMENOPAUSAL VAGINITIS/ATROPHIC VAGINITIS

- **Clinical Features**
  - Dyspareunia
  - Postcoital spotting
  - Mild pruritus
- **Investigations**
  - Atrophy is usually a visual diagnosis: thinning of tissues, erythema, petechiae, bleeding points, dryness on speculum exam
  - Rule out malignancy: especially endometrial cancer
- **Treatment**
  - Local estrogen replacement (ideal): Premarin® cream, VagiFem® tablets, or Estring®
  - Oral or transdermal hormone replacement therapy (if treatment for systemic symptoms is desired)
  - Good hygiene

# INFECTIOUS VULVOVAGINITIS

</table>
Sexually Transmitted Diseases

- see Family Medicine, FM45

TRICHOMEONIASIS
  - see Infectious Vulvovaginitis, Table 14, GY24

CHLAMYDIA

Etiology
  - Chlamydia trachomatis

Epidemiology
  - common bacterial STD in the United States
  - often associated with N. gonorrhoeae

Clinical Features
  - asymptomatic (80% of women)
  - muco-purulent endocervical discharge
  - urethral syndrome: dysuria, frequency, pyuria, no bacteria on culture
  - pelvic pain
  - postcoital bleeding or intermenstrual bleeding (particularly if on OCP and prior history of good cycle control)
  - symptomatic sexual partner

Investigations
  - cervical culture or nucleic acid amplification test
  - obligate intracellular parasite: tissue culture is the definitive standard
  - urine and vaginal tests now available, which are equally or more effective than cervical culture

Treatment
  - doxycycline 100 mg PO bid for 7 d or azithromycin 1 g PO in a single dose
  - if pregnant: azithromycin 1 g PO in a single dose or amoxicillin 500 mg PO tid for 7 d
  - also treat gonorrhea because of high rate of co-infection
  - treat partners
  - reportable disease
  - test of cure for chlamydia required in pregnancy (cure rates lower in pregnant patients) → retest 3-4 wk after initiation of therapy

Screening
  - high risk groups
  - during pregnancy
  - with initiation of OCP (independent risk factor)
Complications
- acute salpingitis, PID
- Fitz-Hugh-Curtis syndrome (liver capsule inflammation)
- reactive arthritis (male predominance, HLA-B27 associated), conjunctivitis, urethritis
- infertility: tubal obstruction from low grade salpingitis
- ectopic pregnancy
- chronic pelvic pain
- perinatal infection: conjunctivitis, pneumonia

GONORRHEA

Etiology
- Neisseria gonorrhoeae
- symptoms and risk factors same as with chlamydia

Investigations
- Gram stain shows Gram-negative intracellular diplococci
- cervical, rectal, and throat culture (if clinically indicated)

Treatment
- single dose of ceftriaxone 250 mg IM plus single dose of azithromycin 1 g PO or doxycycline 100 mg PO bid for 7d
- if pregnant: above regimen or alternate cephalosporin, or single dose of azithromycin 2 g PO
- also treat chlamydia, because of high rate of co-infection
- treat partners
- reportable disease
- screening as with Chlamydia

HUMAN PAPILLOMAVIRUS

Etiology
- common viral STD in the United States
- >200 subtypes, of which >30 are genital subtypes
- HPV types 6 and 11 are classically associated with anogenital warts/condylomata acuminata
- HPV types 16 and 18 are the most oncogenic (classically associated with cervical HSIL)
- types 16, 18, 31, 33, 35, 36, 45 (and others) associated with increased incidence of cervical and vulvar intraepithelial hyperplasia and carcinoma

Clinical Features
- latent infection
  - no visible lesions, asymptomatic
  - only detected by DNA hybridization tests
- subclinical infection
  - visible lesion found during colposcopy or on Pap test
- clinical infection
  - visible wart-like lesion without magnification
  - hyperkeratotic, verrucous or flat, macular lesions
  - vulvar edema

Investigations
- cytology (see Cervical Screening Pap Test, GY41)
  - koilocytosis: nuclear enlargement and atypia with perinuclear halo
- biopsy of lesions at colposcopy
- detection of HPV DNA subtype using nucleic acid probes (not routinely done but can be done in presence of abnormal Pap test to guide treatment)

Treatment
- patient administered
  - podofilox 0.5% solution or gel bid x 3 d in a row (4 d off) then repeat x 4 wk
  - imiquimod (Aldara®) 5% cream 3x/wk qhs x 16 wk
  - provider administered
    - cryotherapy with liquid nitrogen: repeat q1-2wk
    - podophyllin resin 10-25% in tincture of benzoin: weekly
    - trichloroacetic acid (TCA) or bichloroacetic acid weekly (BCA) (80-90%); safe in pregnancy
    - surgical removal/laser

Prevention
- vaccination: Gardasil®, Cervarix® (see Table 24, GY43)
- condoms may not fully protect (areas not covered, must be used every time throughout entire sexual act)
HERPES SIMPLEX VIRUS OF VULVA

Etiology
- 90% are HSV-2, 10% are HSV-1

Clinical Features
- may be asymptomatic
- initial symptoms: present 2-21 d following contact
- prodromal symptoms: tingling, burning, pruritus
- multiple, painful, shallow ulcerations with small vesicles appear 7-10 d after initial infection (absent in many infected persons); lesions are infectious
- inguinal lymphadenopathy, malaise, and fever often with first infection
- dysuria and urinary retention if urethral mucosa affected
- recurrent infections: less severe, less frequent and shorter in duration (especially with HSV-1)

Investigations
- viral culture preferred in patients with ulcer present, however decreased sensitivity as lesions heal
- cytologic smear (Tzanck smear)
  - multinucleated giant cells, acidophilic intranuclear inclusion bodies
- type specific serologic tests for antibodies to HSV-1 and HSV-2
- HSV DNA PCR

Treatment
- first episode
  - acyclovir 400 mg PO tid or 200 mg PO fives times daily x 7-10 d, or famciclovir 250 mg PO tid x 7-10 d, or valacyclovir 1 g PO bid x 7-10 d
- recurrent episode
  - acyclovir 400 mg PO tid or 800 mg PO bid x 5 d, or acyclovir 800 mg PO tid x 2 d; famciclovir and valacyclovir may also be used
- daily suppressive therapy
  - consider if more than 6 recurrences per yr or one every 2 mo
- acyclovir 400 mg PO bid, or famciclovir 250 mg bid, or valacyclovir 0.5-1 g PO OD
- severe disease
  - IV therapy: acyclovir 5-10 mg/kg IV q8h x 2-7 d or until clinical improvement, followed by oral antiviral therapy to complete at least 10 d
- education regarding transmission
- avoid contact from onset of prodrome until lesions have cleared
- use barrier contraception

SYPHILIS

Etiology
- *Treponema pallidum*

Classifications
- primary syphilis
  - 3-4 wk after exposure
  - painless chancre on vulva, vagina, or cervix
  - painless inguinal lymphadenopathy
  - serological tests usually negative, local infection only
- secondary syphilis (can resolve spontaneously)
  - 2-6 mo after initial infection
  - nonspecific symptoms: malaise, anorexia, headache, diffuse lymphadenopathy
  - generalized maculopapular rash: palms, soles, trunk, limbs
  - condylomata lata: anogenital, broad-based fleshy gray lesions
  - serological tests usually positive
- latent syphilis
  - no clinical manifestations; detected by serology only
- tertiary syphilis
  - may involve any organ system
  - neurological: tabes dorsalis, general paresis
  - cardiovascular: aortic aneurysm, dilated aortic root
  - vulvar gumma: nodules that enlarge, ulcerate and become necrotic (rare)
- congenital syphilis
  - may cause fetal anomalies, stillbirths, or neonatal death

Epidemiology of Genital Ulcers
- HSV 70-80%
- 1st Syphilis 5%
- Chancroid <1%
  (Haemophilus ducreyi)
Investigations
- aspiration of ulcer serum or node
- darkfield microscopy (most sensitive and specific diagnostic test for syphilis)
  - spirochetes
- non-treponemal screening tests (VDRL, RPR); nonreactive after treatment, can be positive with other conditions
- specific anti-treponemal antibody tests (FTA-ABS, MHA-TP, TP-PA)
  - confirmatory tests; remain reactive for life (even after adequate treatment)

Treatment
- treatment of primary, secondary, latent syphilis of <1 yr duration
  - benzathine penicillin G 2.4 million units IM single dose
  - treat partners, reportable disease
- treatment of latent syphilis >1 yr duration
  - benzathine penicillin G 2.4 million units IM q1wk x 3 wk
- treatment of neurosyphilis
  - IV aqueous penicillin G 3-4 million units IM q4h x 10-14 d
- screening
  - high risk groups
  - in pregnancy (see Obstetrics, Table 12, OB19)

Complications
- if untreated, 1/3 will experience late complications

HIV
- see Infectious Diseases, ID29

Bartholinitis/Bartholin Gland Abscess

**Etiology**
- often anaerobic and polymicrobial
- *U. urealyticum*, *N. gonorrhoeae*, *C. trachomatis*, *E. coli*, *P. mirabilis*, *Streptococcus* spp., *S. aureus* (rare)
- blockage of duct

**Clinical Features**
- unilateral swelling and pain in inferior lateral opening of vagina
- sitting and walking may become difficult and/or painful

**Treatment**
- sitz baths, warm compresses
- antibiotics: cephalexin x 1 wk
- incision and drainage using local anesthesia with placement of Word catheter (10 French latex catheter) for 2-3 wk
- marsupialization under general anesthetic – more definitive treatment
- rarely treated by removing gland

Pelvic Inflammatory Disease

- up to 20% of all gynecology-related hospital admissions

**Etiology**
- causative organisms (in order of frequency)
  - *C. trachomatis*
  - *N. gonorrhoeae*
  - gonorrhea and chlamydia often co-exist
  - endogenous flora: anaerobic, aerobic, or both
    - *E. coli*, *Staphylococcus*, *Streptococcus*, *Enterococcus*, *Bacteroides*, *Peptostreptococcus*, *H. influenzae*, *G. vaginalis*
  - cause of recurrent PID
  - associated with instrumentation
  - *Actinomyces israelii* (Gram-positive, non acid-fast anaerobe)
  - 1-4% of PID cases associated with IUDs
  - others (TB, Gram-negatives, CMV, *U. urealyticum*, etc.)

**Risk Factors**
- age <30 yr
- risk factors as for chlamydia and gonorrhea
- vaginal douching
- IUD (within first 10 d after insertion)
- invasive gynecologic procedures (D&C, endometrial biopsy)
Clinical Presentation
- up to 2/3 asymptomatic: many subtle or mild symptoms
- common
  - fever >38.3°C
  - lower abdominal pain and tenderness
  - abnormal discharge: cervical or vaginal
- uncommon
  - N/V
  - dysuria
  - AUB
- chronic disease (often due to chlamydia)
  - constant pelvic pain
  - dyspareunia
  - palpable mass
  - very difficult to treat, may require surgery

Investigations
- blood work
  - β-hCG (must rule out ectopic pregnancy), CBC, blood cultures if suspect septicemia
- urine R&M
- speculum exam, bimanual exam
  - vaginal swab for Gram stain, C&S
  - cervical cultures for N. gonorrhoeae, C. trachomatis
  - endometrial biopsy will give definitive diagnosis (rarely done)
- ultrasound
  - may be normal
  - free fluid in cul-de-sac
  - pelvic or tubo-ovarian abscess
  - hydrosalpinx (dilated fallopian tube)
- laparoscopy (gold standard)
  - for definitive diagnosis: may miss subtle inflammation of tubes or endometritis

Treatment
- must treat with polymicrobial coverage
- inpatient if
  - moderate to severe illness
  - atypical infection
  - adnexal mass, tubo-ovarian or pelvic abscess
  - unable to tolerate oral antibiotics or failed oral therapy
  - immunocompromised
  - pregnant
  - adolescent – first episode
  - surgical emergency cannot be excluded (e.g. ovarian torsion)
  - PID is secondary to instrumentation
  - recommended treatment
    - cefotetan 2 g IV q12h or cefoxitin 2 g IV q6h + doxycycline 100 mg PO/IV q12h, or
    - clindamycin 900 mg IV q8h + gentamicin 2 mg/kg IV/IM loading dose followed by 1.5 mg/kg
    - loading dose q8h
  - continue IV antibiotics for 24 h after symptoms have improved then doxycycline 100 mg PO
    - bid to complete 14 d
  - percutaneous drainage of abscess under U/S guidance
  - when no response to treatment, laparoscopic drainage
  - if failure, treatment is surgical (salpingectomy, TAH/BSO)
- outpatient if
  - typical findings
  - mild to moderate illness
  - oral antibiotics tolerated
  - compliance ensured
  - follow-up within 48-72 h (to ensure symptoms not worsening)
  - recommended treatment
    - single dose cefixime 250 mg IM + doxycycline 100 mg PO bid x 14 d ± metronidazole
    - 500 mg PO bid x 14 d
    - consider removing IUD after a minimum of 24 h of treatment
    - N/V
    - reportable disease
    - treat partners
    - consider re-testing for C. trachomatis and N. gonorrhoeae 4-6 wk after treatment if
      documented infection

PID Complications
- I FACE PID
  - Infertility
  - Fitz-Hugh-Curtis syndrome
  - Abscesses
  - Chronic pelvic pain
  - Ectopic pregnancy
  - Peritonitis
  - Intestinal obstruction
  - Disseminated infection (sepsis, endocarditis, arthritis, meningitis)

PID Diagnosis
- Must have:
  - Lower abdominal pain
- Plus one of
  - Cervical motion tenderness
  - Adnexal tenderness
- Plus one or more of
  - High risk partner
  - Temperature >38°C
  - Mucopurulent cervical discharge
  - Positive culture for N. gonorrhoeae, C. trachomatis, E. coli, or other vaginal flora
  - Cul-de-sac fluid, pelvic abscess or inflammatory mass on U/S or bimanual
  - Leukocytosis
  - Elevated ESR or CRP (not commonly used)

Alternative PID Treatments
- Azithromycin (1 g PO weekly x 2 wk)
  + cefixime 250 mg IM x 1
  = metronidazole 500 mg PO bid x 14 d
- Quinolones are no longer recommended for treatment of PID due to quinolone-resistant N. gonorrhoeae

Source: Centers for Disease Control and Prevention. Sexually Transmitted Diseases Treatment Guidelines. MMWR 2010;59(RR-12):1-67
Complications of Untreated PID
- chronic pelvic pain
- abscess, peritonitis
- adhesion formation
- ectopic pregnancy
- infertility
  - 1 episode of PID \(\rightarrow\) 13% infertility
  - 2 episodes of PID \(\rightarrow\) 36% infertility
- bacteremia
- septic arthritis, endocarditis

**Toxic Shock Syndrome**
- see Infectious Diseases, ID24

**Risk Factors**
- tampon use
- diaphragm, cervical cap, or sponge use (prolonged use, i.e. >24 h)
- wound infections
- post-partum infections
- early recognition and treatment of syndrome is imperative as incorrect diagnosis can be fatal

**Clinical Presentation**
- sudden high fever
- sore throat, headache, diarrhea
- erythroderma
- signs of multisystem organ failure
- refractory hypotension
- exfoliation of palmar and plantar surfaces of the hands and feet 1-2 wk after onset of illness

**Treatment**
- remove potential sources of infection (foreign objects and wound debris)
- debride necrotic tissues
- adequate hydration
- penicillinase-resistant antibiotics, e.g. cloxacillin
- steroid use controversial but if started within 72 h, may reduce severity of symptoms and duration of fever

**Sexual Abuse**
- see Family Medicine, FM27, Emergency Medicine, ER28

**Sexual Dysfunction**

**Etiology**
- psychological or emotional: depression, abuse
- hormonal: menopause
- neurologic dysfunction: spinal cord injury
- vascular insufficiency: DM
- drug side effects: \(\beta\)-blockers
- trauma: episiotomy

**Classification**
- lack of desire (60-70% of women)
- lack of arousal
- anorgasmia (5-10%)
  - primary anorgasmia: never before achieved orgasm under any circumstances
  - secondary anorgasmia: was able to achieve orgasms before but now unable to
- dyspareunia (3-6%): painful intercourse, superficial or deep
- vaginismus (15%)
- vulvodynia
- vaginal atrophy
- vulvar vestibulitis: associated with history of frequent yeast infections
- PID

**Treatment**
- lack of desire: assess factors, rule out organic causes, relationship therapy, sensate focus exercises
- anorgasmia: self-exploration/pleasuring, relationship therapy if needed, bridging techniques (different sexual positions, clitoral stimulation during intercourse)
• dyspareunia
  - Kegel and reverse Kegel exercises
  - dilator treatment
  - comfort with self-exam
  - psychotherapy, other behavioral techniques
  - female on top position: allows for control of speed and duration
  - vestibulitis: remove local irritants, change in contraceptive methods, dietary changes (increased citrate, decreased oxalate), and vestibulotomy (rare)
  - vulvodynia: local moisturization, cold compresses, systemic nerve blocking therapy (amitriptyline, gabapentin), topical anesthetics, estrogen cream
  - pain clinic

---

### Menopause

- see Family Medicine, FM42

#### Definitions
- lack of menses for 1 yr
- types of menopause
  - physiological: average age 51 yr (follicular atresia)
  - premature ovarian failure: before age 40 (autoimmune disorder, infection, Turner’s syndrome)
  - iatrogenic (surgical/radiation/chemotherapy)

#### Clinical Features
- associated with estrogen deficiency
  - vasomotor instability (tends to dissipate with time)
    - hot flushes/flashes, night sweats, sleep disturbances, formication, nausea, palpitations
  - urogenital atrophy involving vagina, urethra, bladder
    - dyspareunia, pruritus, vaginal dryness, bleeding, urinary frequency, urgency, incontinence
  - skeletal
    - osteoporosis, joint and muscle pain, back pain
  - skin and soft tissue
    - decreased breast size, skin thinning/loss of elasticity
  - psychological
    - mood disturbance, irritability, fatigue, decreased libido, memory loss

#### Investigations
- increased levels of FSH (>35 IU/L) on day 3 of cycle (if still cycling) and LH (FSH>LH)
- FSH level not always predictive due to monthly variation; use absence of menses for 1 yr to diagnose
- decreased levels of estradiol (later)

#### Treatment
- goal is for individual symptom management
  - vasomotor instability
    - HRT (first line), SSRIs, venlafaxine, gabapentin, propranolol, clonidine
    - acupuncture
  - vaginal atrophy
    - local estrogen: cream (Premarin*), vaginal suppository (VagiFem*), ring (Estring*)
    - lubricants (Replens*)
  - urogenital health
    - lifestyle changes (weight loss, bladder re-training), local estrogen replacement, surgery
  - osteoporosis
    - 1,000-1,500 mg calcium OD, 800-1,000 IU vitamin D, weight-bearing exercise, smoking cessation
    - bisphosphonates (e.g. alendronate)
    - selective estrogen receptor modifiers (SERMs): raloxifene (Evista*) – mimics estrogen effects on bone, avoids estrogen-like action on breast and uterine cancer; does not help hot flashes
    - HRT: second-line treatment (unless for vasomotor instability as well)
  - decreased libido
    - vaginal lubrication, counseling, androgen replacement (testosterone cream or the oral form Andro*):
      - cardiovascular disease
        - management of cardiovascular risk factors
        - mood and memory
          - antidepressants (first line), HRT (augments effect)
        - alternative choices (not evidence-based, safety not established)
          - black cohosh, phytoestrogens, St. John’s wort, gingko biloba, valerian, evening primrose oil, ginseng, Don Quai
Hormone Replacement Therapy

- see Family Medicine, FM42
- primary indication is treatment of menopausal symptoms (vasomotor instability)
- keep doses low (e.g. 0.3 mg Premarin®) and duration of treatment short (<5 yr)

**HRT Components**

- estrogen
  - oral or transdermal (e.g. patch, gel)
  - transdermal preferred for women with hypertriglyceridemia or impaired hepatic function, smokers, and women who suffer from headaches associated with oral HRT
  - low-dose (preferred dose: 0.3 mg Premarin®/25 µg Estradot® patch, can increase if necessary)
- progestin
  - given in combination with estrogen for women with an intact uterus to prevent development of endometrial hyperplasia/cancer

**Table 15. Examples of HRT Regimens**

<table>
<thead>
<tr>
<th>HRT Regimen</th>
<th>Estrogen Dose</th>
<th>Progestin Dose</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unopposed Estrogen</td>
<td>CEE 0.625 mg PO OD</td>
<td>None</td>
<td>If no intact uterus</td>
</tr>
<tr>
<td>Standard-dose</td>
<td>CEE 0.625 mg PO OD</td>
<td>MPA 2.5 mg PO OD</td>
<td>Withdrawal bleeding may occur in a spotty, unpredictable manner. Usually abates after 6-8 mo due to endometrial atrophy. Once patient has become amenorrheic on HRT, significant subsequent bleeding episodes require evaluation (endometrial biopsy).</td>
</tr>
<tr>
<td>Standard-dose cyclic</td>
<td>CEE 0.625 mg PO OD</td>
<td>MPA 5-10 mg PO days 1-14 only, or micronized progesterone 200 mg PO OD days 1-14 only</td>
<td>Bleeding occurs monthly after day 14 of progestin (can continue for yr). PMS-like symptoms (breast tenderness, fluid retention, headache, nausea) are more prominent with cyclic HRT.</td>
</tr>
<tr>
<td>Pulsatile</td>
<td>CEE 0.625 mg PO OD</td>
<td>MPA low-dose</td>
<td>3 d on, 3 d off</td>
</tr>
<tr>
<td>Transdermal</td>
<td>Estroderm®-Estradiol 0.05 mg/d or 0.1 mg/d Estalis®-Estradiol 140 µg/d or 250 µg/d</td>
<td>Estroderm®-MPA 2.5 mg PO OD Estalis®-NEA 50 µg/d</td>
<td>Use patch twice weekly. Can use oral progestins (Estroderm®). Combined patches available (Estalis®).</td>
</tr>
<tr>
<td>Topical</td>
<td>Estrace® 2.4 g/d x 1-2 wk, 1 g/d maintenance Premarin® 0.5-2 g/d for 21 d then off 7 d for vaginal atrophy, 0.5 g/d for 21 d then off 7 d or twice/wk for dyspareunia Estragyn® 2-4 g/d</td>
<td>Crinone® 4% or 9% (45 or 90 mg applicator)</td>
<td>If simultaneously taking oral estrogen tablet, may need to adjust dosing. If intact uterus, also take progesterone</td>
</tr>
</tbody>
</table>

CEE = conjugated equine estrogen (e.g. Premarin®); MPA = medroxyprogesterone acetate (e.g. Provera®); NEA = norethindrone acetate
Consider lower dose regimen, PREMPRO® 0.45/1.5 (Premarin® 0.45 mg and Provera® 1.5 mg); Estrace® (topical 17β-estradiol) = 0.1 mg active ingredient/g; Premarin® (topical CEE) = 0.625 mg active ingredient/g; Estragyn® (topical estriol) = 1 mg active ingredient/g

**Side Effects of HRT**

- abnormal uterine bleeding
- mastodynia – breast tenderness
- edema, bloating, heartburn, nausea
- mood changes (progesterone)
- can be worse in progesterone phase of combined therapy

**Contraindications to HRT**

- absolute
  - acute liver disease
  - undiagnosed vaginal bleeding
  - known or suspected uterine cancer/breast cancer
  - acute vascular thrombosis or history of severe thrombophlebitis or thromboembolic disease
  - cardiovascular disease
- relative
  - pre-existing uncontrolled HTN
  - uterine fibroids and endometriosis
  - familial hyperlipidemias
  - migraine headaches

---

**Menopause Pathophysiology**

Degenerating theca cells fail to react to endogenous gonadotropins (FSH, LH)

- Less estrogen is produced
- Decreased negative feedback on hypothalamic-pituitary-adrenal axis
- Increased FSH and LH
- Stromal cells continue to produce androgens as a result of increased LH stimulation

**Absolute Contraindications to HRT**

ABCD
- Acute liver disease
- Undiagnosed vaginal bleeding
- Cancer (breast/uterine), Cardiovascular disease
- DVT (thromboembolic disease)
family history of estrogen-dependent cancer  
chronic thrombophlebitis  
DM (with vascular disease)  
gallbladder disease, hypertriglyceridemia, impaired liver function (consider transdermal estrogen)  
fibrocystic disease of the breasts

WOMEN'S HEALTH INITIATIVE (launched in 1991)  
- two non-randomized studies investigating health risks and benefits of HRT in healthy postmenopausal women 50-79 yr old  
- continuous combined HRT (CEE 0.625 mg + MPA 2.5 mg OD) in 16,608 women with an intact uterus  
- estrogen-alone (CEE 0.625 mg) in 10,739 women with a previous hysterectomy  
- both arms of the trial were stopped early because of evidence of increased risk of breast cancer, stroke, PE, and CHD in the combined HRT arm, and increased risk of stroke with no CHD benefits in the estrogen-alone arm  
- the apparent increase in CHD was in disagreement with results of previous observational trial  
- results of the WHI study have since been challenged and revision of how CHD was diagnosed led to loss of statistical significance of the results  
- benefits and risks reported as number of cases per 10,000 women each yr

The apparent increase in CHD was in disagreement with results of previous observational trial  
- one additional case with estrogen-alone  
- 6 fewer cases with combined HRT (WHI)  
- Colon Cancer: 8 additional cases with combined HRT, and 12 additional cases for estrogen-alone (WHI)  
- DVT/PE: 18 additional cases with combined HRT, and 9 additional cases for estrogen-alone (WHI)  
- CHD: 7 additional MIs with combined HRT (WHI); secondary analysis suggests greater absolute risk for women aged > 70 yr and for women who start HRT > 10 yr post-menopause  
- Breast Cancer: 8 additional cases with combined HRT (WHI) Risk only increased after > 5 yr of combined HRT use; no increased risk for estrogen-alone  
- Dementia and Mild Cognitive Impairment: 50% greater risk of developing dementia in women taking estrogen-alone after age 65; risk is greater for women taking combined HRT; risk of developing dementia was reduced for women taking HRT before age 65

Table 16. HRT Benefits vs. Risks

<table>
<thead>
<tr>
<th>Benefits</th>
<th>Risks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vasomotor Symptoms: less frequent and severe with use of either combined or estrogen-alone HRT</td>
<td>Stroke: 8 additional cases with combined HRT, and 12 additional cases for estrogen alone (WHI)</td>
</tr>
<tr>
<td>Osteoporosis: 5 fewer cases of hip fractures and 47 fewer cases of all fractures with combined HRT; 6 fewer cases of hip fractures with estrogen alone</td>
<td>DVT/PE: 18 additional cases with combined HRT, and 9 additional cases for estrogen-alone (WHI)</td>
</tr>
<tr>
<td>Colon Cancer: 6 fewer cases with combined HRT (WHI) One additional case with estrogen-alone</td>
<td>CHD: 7 additional MIs with combined HRT (WHI); secondary analysis suggests greater absolute risk for women aged &gt; 70 yr and for women who start HRT &gt; 10 yr post-menopause</td>
</tr>
<tr>
<td></td>
<td>Breast Cancer: 8 additional cases with combined HRT (WHI) Risk only increased after &gt; 5 yr of combined HRT use; no increased risk for estrogen-alone</td>
</tr>
<tr>
<td></td>
<td>Dementia and Mild Cognitive Impairment: 50% greater risk of developing dementia in women taking estrogen-alone after age 65; risk is greater for women taking combined HRT; risk of developing dementia was reduced for women taking HRT before age 65</td>

</tbody>
</table>

Urogynecology

Pelvic Relaxation/Prolapse

Etiology
- relaxation, weakness, or defect in the cardinal and uterosacral ligaments which normally maintain the uterus in an anteflexed position and prevent it from descending through the urogenital diaphragm (i.e. levator ani muscles)
- related to
  - vaginal childbirth
  - aging
  - decreased estrogen (post-menopause)
  - following pelvic surgery
  - increased intra-abdominal pressure (obesity, chronic cough, constipation, ascites, heavy lifting)
  - congenital (rarely)
  - ethnicity (Caucasian women > Asian or African women)
  - collagen disorders

GENERAL CONSERVATIVE TREATMENT
(for pelvic relaxation/prolapse and urinary incontinence)
- Kegel exercises
- local vaginal estrogen therapy
- vaginal pessary (intravaginal suspension disc)
Table 17. Pelvic Prolapse

<table>

</table>

Urinary Incontinence

- see Urology, U5

STRESS INCONTINENCE

Definition
- involuntary loss of urine with increased intra-abdominal pressure (coughing, laughing, sneezing, walking, running)
Risk Factors for Stress Incontinence in Women
• pelvic prolapse
• pelvic surgery
• vaginal delivery
• hypoestrogenic state (post-menopause)
• age
• smoking
• neurological/pulmonary disease

Treatment
• see General Conservative Treatment, GY33
• surgical
  ▪ tension-free vaginal tape (TVT), tension-free obturator tape (TOT), prosthetic/fascial slings or retropubic bladder suspension (Burch or Marshall-Marchetti-Krantz procedures)

URGE INCONTINENCE

Definition
• urine loss associated with an abrupt, sudden urge to void
• “overactive bladder”
• diagnosed based on symptoms

Etiology
• idiopathic (90%)
• detrusor muscle overactivity (“detrusor instability”)

Associated Symptoms
• frequency, urgency, nocturia, leakage

Treatment
• behavior modification (reduce caffeine/liquid, smoking cessation, regular voiding schedule)
• Kegel exercises
• medications
  ▪ anticholinergics: oxybutinin (Ditropan®), tolterodine (Detrol®), solifenacin (VESIcare®)
  ▪ tricyclic antidepressants: imipramine

ENDOMETRIAL CARCINOMA

Epidemiology
• most common gynecological malignancy in North America (40%); 4th most common cancer in women
• 2-3% of women develop endometrial carcinoma during lifetime
• mean age is 60 yr
• majority are diagnosed in early stage due to detection of symptoms
• 85-90% 5 yr survival for stage I disease
• 70-80% overall 5 yr survival for all stages

Risk Factors
• Type I: excess estrogen (estrogen unopposed by progesterone)
  ▪ obesity
  ▪ PCOS
  ▪ unbalanced HRT (balanced HRT is protective)
  ▪ nulliparity
  ▪ late menopause
  ▪ estrogen-producing ovarian tumors (e.g. granulosa cell tumors)
  ▪ HNPCC (hereditary non-polyposis colorectal cancer)/Lynch II syndrome
  ▪ tamoxifen
• Type II: not estrogen-related
  ▪ possibly tamoxifen

Classification and Clinical Features
• Type I (well-differentiated endometrioid adenocarcinoma) ~80% of cases:
  ▪ postmenopausal bleeding in majority, abnormal uterine bleeding in majority of affected pre-menopausal women (menorrhagia, intermenstrual bleeding)
• Type II (serous, clear cell carcinoma, grade 3 endometrioid, undifferentiated, carcinosarcoma) ~15% of cases:
  ▪ may not present with bleeding in early stage, more likely to present with advanced stage disease with symptoms like ovarian cancer (i.e. bloating, bowel dysfunction, pelvic pressure)

Investigations
• endometrial sampling
  ▪ office endometrial biopsy
  ▪ D&C ± hysteroscopy
• ± pelvic ultrasound (in women where adequate endometrial sampling not feasible without invasive methods)
  ▪ not acceptable as alternative to pelvic exam or endometrial sampling to rule out cancer

Table 18. FIGO Staging of Endometrial Cancer (2009)

<table>
<thead>
<tr>
<th>Stage</th>
<th>Description</th>
<th>Stage</th>
<th>Description</th>
</tr>

<td>Distant mets, including intra-abdominal mets ± inguinal LNs</td>
</tr>
</tbody>
</table>

FIGO: International Federation of Gynecology and Obstetrics
*Note: endocervical glandular involvement is now considered as Stage I (previously Stage II)

Spread
• direct extension is most common
• lymphatic spread to pelvic and para-aortic nodes
• transtubal dissemination to peritoneal cavity
• hematogenous spread (usually to lungs, liver)

Treatment
• surgical: hysterectomy/bilateral salpingo-oophorectomy (BSO) and pelvic washings ± pelvic and para-aortic node dissection ± omentectomy
  ▪ goals: diagnosis, staging, treatment, defining optimal adjuvant treatment
  ▪ laparoscopic approach associated with improved quality of life (optimal for most patients)
• adjuvant radiotherapy (for improved local control in patients at risk for local recurrence) and adjuvant chemotherapy (in patients at risk for distant recurrence or with metastatic disease): based on presence of poor prognostic factors in definitive pathology
• chemotherapy: often used for recurrent disease (especially if high grade or aggressive histology)
• hormonal therapy: progestins can be used for recurrent disease (especially if low grade)

UTERINE SARCOMA
• rare; 2-6% of all uterine malignancies
• arise from stromal components (endometrial stroma, mesenchymal or myometrial tissues)
• behave more aggressively and are associated with worse prognosis than endometrial carcinoma; 5 yr survival is 35%
• vaginal bleeding is most common presenting symptom

Risk Factors for Endometrial Cancer
COLD NUT
Cancer (ovarian, breast, colon)
Obesity
Late menopause
DM
Nulliparity
Unopposed estrogen: PCOS, anovulation, HRT
tamoxifen: chronic use

Postmenopausal bleeding = endometrial cancer until proven otherwise (95% present with vaginal bleeding)

An endometrial thickness of 5 mm or more is considered abnormal in a postmenopausal woman with vaginal bleeding

True Pelvis
Area of pelvis between pelvic inlet and outlet, i.e. it does not include the abdominal contents in the pelvis found above the pelvic inlet

Prognostic Factors
Most important is FIGO stage
Other Prognostic Factors:
• Age
• Grade
• Histologic subtype
• Depth of myometrial invasion
• Presence of lymphovascular space involvement (LVSI)
• Hormone receptor status

Uterine Sarcoma – Symptoms
BAD-P
Bleeding
Abdominal distention
Foul smelling vaginal Discharge
Pelvic Pressure

<td></td>
<td>• Rapidly enlarging fibroids in a pre-menopausal woman</td>
<td></td>
<td>• Poor outcomes overall, even for early stage disease</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Enlarging fibroids in a postmenopausal woman</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2. Endometrial Stromal Sarcoma (ESS)</td>
<td>• Accounts for 10-15%</td>
<td>• Abnormal uterine bleeding</td>
<td>• Diagnosed by histology of endometrial biopsy or DBc</td>
<td>• Hysterectomy/BSO (remove ovaries as ovarian hormones may stimulate growth)</td>
</tr>
<tr>
<td></td>
<td>• Usually presents in perimenopausal or postmenopausal women with abnormal uterine bleeding</td>
<td>• Good prognosis</td>
<td></td>
<td>• No routine pelvic lymphadenectomy</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• Adjuvant therapy based on stage and histologic features (hormones and/or radiation)</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>• Hormonal therapy (progestins) may be used for metastatic disease</td>
</tr>
<tr>
<td>3. Undifferentiated Sarcoma</td>
<td>• Accounts for 5-10%</td>
<td>• Severe nuclear pleomorphism, high mitotic activity, tumor cell necrosis, and lack smooth muscle or endometrial stromal differentiation</td>
<td>• Often found incidentally post-operatively for abnormal bleeding</td>
<td>• Treatment primarily surgical</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Poor prognosis</td>
<td></td>
<td>• Radiation and/or chemotherapy for advanced diseased or unresectable disease</td>
</tr>
<tr>
<td><strong>MIXED TYPE</strong></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>4. Adenosarcoma</td>
<td>• The rarest of the uterine sarcoma</td>
<td>• Present with abnormal vaginal bleeding</td>
<td>• Mixture of benign epithelium with malignant low-grade sarcoma</td>
<td>• Treatment is surgical with TAH/BSO</td>
</tr>
<tr>
<td></td>
<td>• Mixed tumor of low malignant potential</td>
<td>• Polypoid mass in uterine cavity</td>
<td>• Often found incidentally at time of hysterectomy for PMB</td>
<td></td>
</tr>
<tr>

</tbody>
</table>

Ovary

**BENIGN OVARIAN TUMORS**
- see Table 21
- many are asymptomatic
- usually enlarge slowly, if at all
- may rupture or undergo torsion, causing pain
  - pain associated with torsion of an adnexal mass usually originates in the iliac fossa and radiates to the flank
- peritoneal irritation may result from an infarcted tumor – rare

**Ovarian Tumor Markers**
- Epithelial cell – CA-125
- Stromal
  - Granulosa cell – inhibin
  - Sertoli-Leydig – androgens
- Germ cell
  - Dysgerminoma – LDH
  - Yolk sac – AFP
- Choriocarcinoma – β-hCG
- Immature Teratoma – none
- Embryonal cell – AFP + β-hCG
MALIGNANT OVARIAN TUMORS
• see Table 21

Epidemiology
• lifetime risk 1.4% (1/70)
• in women >50 yr, more than 50% of ovarian tumors are malignant
• causes more deaths in North America than all other gynecologic malignancies combined
• 4th leading cause of cancer death in women
• 65% epithelial; 35% non-epithelial
• 5-10% of epithelial ovarian cancers are related to hereditary predisposition

Risk Factors (for epithelial ovarian cancers)
• excess estrogen
  ▪ nulliparity
  ▪ early menarche/late menopause
• age
• family history of breast, colon, endometrial, ovarian cancer
• race: Caucasian

Protective Factors (for epithelial ovarian cancers)
• OCP: likely due to ovulation suppression (significant reduction in risk even after 1 yr of use)
• pregnancy/breastfeeding
• tubal ligation (recently questioned)
• hysterectomy (without removal of ovaries)
• BSO (prophylactic surgery performed for this reason in high risk women – i.e. BRCA mutation carriers)

Screening
• no effective method of mass screening
• routine CA-125 level measurements or U/S not recommended
  ▪ high false positive rates
• controversial in high risk groups: transvaginal U/S and CA-125, starting age 30 (no consensus on interval)
  ▪ familial ovarian cancer (>1 first degree relative affected, BRCA-1 mutation)
  ▪ other cancers (e.g. endometrial, breast, colon)
• BRCA-1 or BRCA-2 mutation: may recommend prophylactic bilateral oophorectomy after age 35 or when child-bearing is completed

Clinical Features
• most women with epithelial ovarian cancer present with advanced stage disease since often “asymptomatic” until disseminated disease (symptoms with early stage disease are vague and non-specific)
• when present, symptoms may include
  ▪ abdominal symptoms (nausea, bloating, dyspepsia, anorexia, early satiety)
  ▪ symptoms of mass effect
    ✤ increased abdominal girth – from ascites or tumor itself
    ✤ urinary frequency
    ✤ constipation
  ▪ postmenopausal bleeding; irregular menses if pre-menopausal (rare)

Low Malignant Potential (also called “Borderline”) Tumors
• pregnancy, OCP, and breastfeeding are protective factors
• ~15% of all epithelial ovarian tumors
• tumor cells display malignant characteristics histologically, but no invasion is identified
• able to metastasize, but not commonly
• treated primarily with surgery (BSO/omental biopsy ± hysterectomy)
  ▪ NO proven benefit of chemotherapy
• generally slow growing, excellent prognosis
  ▪ 5 yr survival >99%
• recurrences tend to occur late, may be associated with low grade serous carcinoma

Investigation of Suspicious Ovarian Mass

- women with suspected ovarian cancer based on history, physical, or investigations should be referred to a gynecologic oncologist
  - bimanual examination
  - solid, irregular, or fixed pelvic mass is suggestive of ovarian cancer
  - RMI (Risk of Malignancy Index) is best tool available to assess likelihood of ovarian malignancy and need for pre-operative gynecologic oncology referral (see sidebar)
  - blood work: CA-125 for baseline, CBC, liver function tests, electrolytes, creatinine
  - radiology
    - bone scan or PET scan not indicated
    - transvaginal ultrasound best to visualize ovaries
    - CT scan abdomen and pelvis to look for metastatic disease
  - try to rule out other primary source if suspected, based on:
    - occult blood per rectum: endoscopy ± barium enema
    - gastric symptoms, gastroscopy ± upper GI series
    - abnormal vaginal bleeding, endometrial biopsy to rule out concurrent endometrial cancer, colposcopy ± ECC to rule out cervical cancer if abnormal cervix
    - breast lesion identified or risk factors present: mammogram

FIGO = International Federation of Gynecology and Obstetrics
Cervix

BENIGN CERVICAL LESIONS

- Nabothian cyst/inclusion cyst
  - no treatment required
- endocervical polyps
  - treatment is polypectomy (office procedure)

MALIGNANT CERVICAL LESIONS

Epidemiology
- majority are SCCs (95%); adenocarcinomas increasing (5%); rare subtypes include SCC, adenosquamous
- 8,000 deaths annually in North America
- annual Pap test reduces a woman’s chance of dying from cervical cancer from 0.4% to 0.05%
- average age at presentation: 52 yr old

Etiology
- at birth, vagina is lined with squamous epithelium; columnar epithelium lines only the endocervix and the central area of the ectocervix (original squamocolumnar junction)
- during puberty, estrogen stimulates eversion of a single columnar layer (ectopy), thus exposing it to the acidic pH of the vagina, leading to metaplasia (change of exposed epithelium from squamous to columnar)
  - a new squamocolumnar junction forms as a result
- the transformation zone (TZ ) is the area located between the original and the current squamocolumnar junction
- the majority of dysplasias and cancers arise in the TZ of the cervix
- must have active metaplasia in presence of inducing agent (HPV) to get dysplasia
- dysplasia → carcinoma in situ (CIS) → invasion
- slow process (~10 yr on average)
- growth is by local extension
- metastasis occurs late

Risk Factors
- HPV infection
  - see Sexually Transmitted Diseases, GY26
  - high risk of neoplasia associated with types 16, 18
  - low risk of neoplasia associated with types 6, 11
  - >99% of cervical cancers contain one of the high risk HPV types
- high risk behaviors (risk factors for HPV infection)
  - multiple partners
  - other STDs (HSV, trichomonas)
  - early age at first intercourse
  - high risk male partner
  - smoking
- at-risk groups include:
  - sex-trade workers
  - low socioeconomic status

Cervical Cancer Screening Guidelines (Pap Test)
- see Family Medicine, FM5

Clinical Features
- SCC: exophytic, fungating tumor
- adenocarcinoma: endophytic, with barrel-shaped cervix
- early
  - asymptomatic
  - discharge: initially watery, becoming brown or red
  - postcoital bleeding
- late
  - 80-90% present with bleeding: either postcoital, postmenopausal or irregular bleeding
  - pelvic or back pain (extension of tumor to pelvic walls)
  - bladder/bowel symptoms
- signs
  - friable, raised, reddened, or ulcerated area visible on cervix

Ultrasound Findings (1 pt for each)
- Multilocular cyst
- Evidence of solid areas
- Evidence of metastases
- Presence of ascites
- Bilateral lesions
  - U = 1 (for U/S scores of 0 or 1)
  - U = 4 (for U/S scores of 2-5)

Menopausal Status
- Postmenopausal: M = 4
- Premenopausal: M = 1

Absolute Value of CA-125 Serum Level
- For RMI >200: Gynecologic oncology referral is recommended

A Risk of Malignancy Incorporating CA125, Ultrasound, and Menopausal Status for the Accurate Pre-Operative Diagnosis of Ovarian Cancer

RMI = U x M x CA-125

Ultrasound Findings (1 pt for each)
- Multilocular cyst
- Evidence of solid areas
- Evidence of metastases
- Presence of ascites
- Bilateral lesions
  - U = 1 (for U/S scores of 0 or 1)
  - U = 4 (for U/S scores of 2-5)

Menopausal Status
- Postmenopausal: M = 4
- Premenopausal: M = 1

Absolute Value of CA-125 Serum Level
- For RMI >200: Gynecologic oncology referral is recommended

Figure 17. The cervix

Gland opening

External os

Original squamo-columnar junction

New squamo-columnar junction

© Ayalah Hutchins

CA-125 is indicated for monitoring response to treatment

Malignant Ovarian Tumor Prognosis

5 yr Survival
- Stage I: 75-95%
- Stage II: 60-75%
- Stage III: 23-41%
- Stage IV: 11%

Causes of Elevated CA-125
- Age influences reliability of test as a tumor marker
- 50% sensitivity in early stage ovarian cancer (poor) — therefore not good for screening

Malignant
- Gyne: ovary, uterus
- Non-Gyne: pancreas, stomach, colon, rectum

Non-Malignant
- Gyne: benign ovarian neoplasm, endometriosis, pregnancy, fibroids, PID
- Non-Gyne: cirrhosis, pancreatitis, renal failure

Figure 17. The cervix

© Ayalah Hutchins
Diagnosis

- apply acetic acid and identify acetowhite lesions, punctuation, mosaicism, and abnormal blood vessels to guide cervical biopsy
- endocervical curettage (ECC) if entire lesion is not visible or no lesion visible
- diagnostic excision (LEEP) if lesion extends into endocervical canal
  - positive ECC
  - discrepancy between Pap test results and colposcopy
  - microinvasive carcinoma
- consider cold knife conization (in OR) if glandular abnormality suspected based on cytology or colposcopic findings due to concern for margin interpretation
- tests permitted for FIGO clinical staging include: physical exam (including EUA), cervical biopsy (including cone biopsy), proctoscopy/cystoscopy, IVP, ultrasound liver/kidneys, CXR, LFTs
- MRI and/or CT and/or PET scan often done to facilitate planning of radiation therapy, results do not influence clinical stage

Treatment: Prevention and Management

Prevention: HPV Vaccine

- two vaccines currently approved (Gardasil®, Cervarix®)

Table 23. Comparison of Two Vaccines against Human Papillomavirus (HPV)

</tbody>
</table>

- should be administered before onset of sexual activity (i.e. before exposure to virus) for optimal benefit of vaccination
- may be given at the same time as hepatitis B or other vaccines using a different injection site
- not for treatment of active infections
- most women will not be infected with all four types of the virus at the same time, therefore vaccine is still indicated for sexually active females or those with a history of previous HPV infection or HPV-related disease
- conception should be avoided until 30 d after last dose of vaccination

The Bethesda Classification System is based on cytological results of a Pap test that permits the examination of cells but not tissue structure; cervical intraepithelial neoplasia (CIN) or cervical carcinoma is a histological diagnosis, requiring a tissue sample via biopsy of suspicious lesions seen during colposcopy.

Efficacy of Human Papillomavirus (HPV)-16/18 AS04-Adjuvanted Vaccine Against Cervical Infection and Precancer Caused by Oncogenic HPV Types (PATRICIA): Final Analysis of a Double-Blind, Randomized Study in Young Women

Lancet 2009;374:301-314

Study: Phase III double-blind, controlled RCT.

Patients: 18,644 women aged 15-25.

Selected Outcomes: Development of HPV-16/18 associated CIN II+ was the primary outcome. Secondary to this were persistence of infections with HPV-16, HPV-18, or other oncogenic HPV types.

Selected Results: Efficacy against development of HPV-16/18 associated CIN II+ was 98.1% (p<0.0001). High levels of cross-protection were observed for persistent infection with HPV-31 and HPV-45 and HPV-31 or HPV-45 associated CIN II+.

Conclusions: The HPV-16/18 AS04-adjuvanted vaccine protected against HPV-16/18 associated CIN II+ lesions and lesions associated with HPV-31, HPV-33, and HPV-45.
Table 24. Management of Patients Abnormal Cervical Histology and Cervical Cancer

<table>
<thead>
<tr>
<th>Management</th>
</tr>
</thead>
<tbody>
<tr>
<td>CIN I</td>
</tr>
<tr>
<td>• Preferred option for biopsy-proven CIN I is observation</td>
</tr>
<tr>
<td>• Repeat assessment and cytology in 12 mo</td>
</tr>
<tr>
<td>• Management according to cytology results</td>
</tr>
<tr>
<td>If after HSIL or AGC</td>
</tr>
<tr>
<td>• Cytology and histology should be reviewed</td>
</tr>
<tr>
<td>• If discrepancy remains, excisional biopsy may be considered</td>
</tr>
<tr>
<td>CIN II and CIN III</td>
</tr>
<tr>
<td>Women ≥25 yr</td>
</tr>
<tr>
<td>• CIN II or III should be treated</td>
</tr>
<tr>
<td>• Excisional procedures preferred for CIN III</td>
</tr>
<tr>
<td>• Those with positive margins should have follow-up with colposcopy and directed biopsies and/or endocervical curettage</td>
</tr>
<tr>
<td>• Treatment for recurrent CIN II or III should be by excision</td>
</tr>
<tr>
<td>Women &lt;25 yr</td>
</tr>
<tr>
<td>• Pathologist should be asked to clarify whether lesion is CIN II or CIN III</td>
</tr>
<tr>
<td>• CIN II: observe with colposcopy at 6-mo intervals for up to 24 mo before treatment considered</td>
</tr>
<tr>
<td>• CIN III: should be treated</td>
</tr>
<tr>
<td>During pregnancy:</td>
</tr>
<tr>
<td>• CIN II or III suspected or diagnosed during pregnancy, repeat colposcopy and treatment delayed until 8-12 wk after delivery</td>
</tr>
<tr>
<td>Stage IA1 (no LVSI)</td>
</tr>
<tr>
<td>• Trachelectomy (removal of only the cervix) if future fertility desired (and lesion ≤2 cm)</td>
</tr>
<tr>
<td>• Simple hysterectomy if future fertility is not desired</td>
</tr>
<tr>
<td>Stage IA2, IB1</td>
</tr>
<tr>
<td>• Typically treated with radical hysterectomy and pelvic lymphadenectomy (sentinel nodes under study)</td>
</tr>
<tr>
<td>• Equal cure rates may be obtained with primary radiation therapy; advantage of surgery: may accurately stage and grade and more targeted adjuvant therapy</td>
</tr>
<tr>
<td>• Advantage is that ovaries can be spared if pre-menopausal</td>
</tr>
<tr>
<td>• For fertility preservation, may have radical trachelectomy (removal of cervix and parametria) and nodes instead of radical hysterectomy for early-stage disease</td>
</tr>
<tr>
<td>• Concurrent chemoradiation therapy if adverse high risk prognostic factors on radical surgical specimen, such as: positive pelvic lymph nodes, positive parametria, and/or positive margins</td>
</tr>
<tr>
<td>Stages IB2 (&gt;4 cm), II, III, IV</td>
</tr>
<tr>
<td>• Primary chemoradiation therapy</td>
</tr>
<tr>
<td>• PET/CT to grade: evaluate pelvic and para-aortic nodes</td>
</tr>
<tr>
<td>• For positive nodes on PET: primary chemoradiation with extended field RT</td>
</tr>
<tr>
<td>• Hysterectomy generally not suggested following primary treatment with curative intent</td>
</tr>
</tbody>
</table>

Abnormal Pap Tests in Pregnancy
- incidence: 1/2,200
- Pap test at all initial prenatal visits
  - if abnormal Pap or suspicious lesion, refer to colposcopy
- if diagnostic conization required, should be deferred until second trimester (T2) to minimize risk of pregnancy loss
- if invasive cancer ruled out, management of dysplasia deferred until completion of pregnancy (may deliver vaginally)
- if invasive cancer present, management depends on prognostic factors, degree of fetal maturity, and patient wishes
  - general recommendations in T1: consider pregnancy termination, management with either radical surgery (hysterectomy vs. trachelectomy if desires future fertility), or concurrent chemoradiation therapy
  - recommendations in T2/T3: delay of therapy until viable fetus and C/S for delivery with concurrent radical surgery or subsequent concurrent chemoradiation therapy

Vulva

BENIGN VULVAR LESIONS

Non-Neoplastic Disorders of Vulvar Epithelium
- biopsy is necessary to make diagnosis and/or rule out malignancy
- hyperplastic dystrophy (squamous cell hyperplasia)
  - surface thickened and hyperkeratotic
  - pruritus most common symptom
- typically postmenopausal women
- treatment: 1% fluorinated corticosteroid ointment bid for 6 wk

CDC Advisory Committee on Immunization Practices (ACIP) Recommends Quadrivalent HPV4 Vaccine for Males
- Routine HPV4 vaccination for males aged 11-12 as a 3-dose series
- HPV4 vaccination for males aged 13-21 who have not been vaccinated previously or have not completed the 3-dose series
- Males 22-26 yr of age may be vaccinated

Source: Centers for Disease Control and Prevention. Recommendations on the Use of Quadrivalent Human Papillomavirus Vaccine in Males – Advisory Committee on Immunization Practices (ACIP), 2011. MMWR 2011;60:1705-1708

Cervical Cancer Prognosis
5 yr Survival
- Stage 0 99%
- Stage I 75%
- Stage II 55%
- Stage III 30%
- Stage IV 7%
- Overall 50-60%

Cervical cancer is most prevalent in developing countries and therefore is the only gynecologic cancer that uses clinical staging; this facilitates consistent international staging with countries that do not have technologies, such as CT and MRI

Cervical Cancer Prognosis

5 yr Survival
- Stage 0 99%
- Stage I 75%
- Stage II 55%
- Stage III 30%
- Stage IV 7%
- Overall 50-60%

Any suspicious lesion of the vulva should be biopsied
• lichen sclerosis
  - subepithelial fat becomes diminished; labia become thin, atrophic, with membrane-like epithelium and labial fusion
  - pruritus, dyspareunia, burning
  - figure of 8’ distribution
  - most common in postmenopausal women but can occur at any age
  - treatment: ultrapotent topical steroid 0.05% clobetasol x 2-4 wk then taper down
  - mixed dystrophy (lichen sclerosis with epithelial hyperplasia)
    - hyperkeratotic areas with areas of thin, shiny epithelium
    - treatment: fluorinated corticosteroid ointment

Tumors
• papillary hidradenoma, nevus, fibroma, hemangioma

MALIGNANT VULVAR LESIONS

Epidemiology
• 5% of genital tract malignancies
• 90% SCC; remainder melanomas, basal cell carcinoma, Paget’s disease, Bartholin’s gland carcinoma
  - Type I disease: HPV-related (50-70%)
    - more likely in younger women
    - 90% of VIN contain HPV DNA (usually types 16, 18)
  - Type II disease: not HPV-related, associated with current or previous vulvar dystrophy
    - usually postmenopausal women

Risk Factors
• HPV infection
• VIN: precancerous change which presents as multicentric white or pigmented plaques on vulva (may only be visible at colposcopy)
  - progression to cancer rarely occurs with appropriate management
  - treatment: local excision (i.e. superficial vulvectomy ± split thickness skin grafting to cover defects if required) vs. ablative therapy (i.e. laser, cautery) vs. local immunotherapy (imiquimod)

Clinical Features
• many patients asymptomatic at diagnosis (many also deny or minimize symptoms)
• most lesions occur on the labia majora, followed by the labia minora (less commonly on the clitoris or perineum)
• localized pruritus or lesion most common
• less common: raised red, white or pigmented plaque, ulcer, bleeding, discharge, pain, dysuria
• patterns of spread
  - local
  - groin lymph nodes (usually inguinal → pelvic nodes)
  - hematogenous

Investigations
• ± colposcopy
• ALWAYS biopsy any suspicious lesion

Prognosis
• depends on stage – particularly nodal involvement (single most important predictor followed by tumor size)
• lesions >4 cm associated with poorer prognosis
• overall 5 yr survival rate: 79%

Fallopian Tube

• least common site for carcinoma of female reproductive system (0.3%)
• usually serous epithelial carcinoma
• recently considered to be origin of serous ovarian cancer
• more common in fifth and sixth decade

Clinical Features
• classic triad present in minority of cases, but very specific
  - watery discharge (most specific) = “hydrops tubae profluens”
  - vaginal bleeding or discharge in 50% of patients
  - crampy lower abdominal/pelvic pain
• most patients present with a pelvic mass (see Ovarian Cancer, GY37 for guidelines regarding diagnosis/investigation)

Treatment
• as for malignant epithelial ovarian tumours
Gestational Trophoblastic Disease/Neoplasia

- refers to a spectrum of proliferative abnormalities of the trophoblast

Epidemiology
- 1/1,000 pregnancies
- marked geographic variation – as high as 1/125 in Taiwan
- 80% benign, 15% locally invasive, 5% metastatic
- cure rate >95%

HYDATIDIFORM MOLE (Benign GTD)

Complete Mole
- most common type of hydatidiform mole
- diffuse trophoblastic hyperplasia, hydropic swelling of chorionic villi, no fetal tissues, or membranes present
- 46XX or 46XY; chromosomes completely of paternal origin (90%)
- 2 sperm fertilize empty egg or 1 sperm with reduplication
- 15-20% risk of progression to malignant sequelae
- risk factors:
  - geographic (South East Asia most common)
  - others (maternal age >40 yr, β-carotene deficiency, vitamin A deficiency) – not proven
- clinical features:
  - often present during apparent pregnancy with abnormal symptoms/findings:
    - vaginal bleeding (97%)
    - excessive uterine size for LMP (51%)
    - theca-lutein cysts >6 cm (50%)
    - preeclampsia (27%)
    - hyperemesis gravidarum (26%)
    - hyperthyroidism (7%)
    - β-hCG >100,000 IU/L
    - β-hCG >100,000 IU/L
    - no fetal heart beat detected

Partial (or Incomplete) Mole
- focal trophoblastic hyperplasia and hydropic villi are associated with fetus or fetal parts
- often triploid (XXY, XYY, XXX) with chromosome complement from both parents
  - usually related to single ovum fertilized by two sperm
  - low risk of progression to malignant sequelae (<4%)
  - associated with fetus, which may be growth-restricted, and/or have multiple congenital malformations
- clinical features:
  - typically present similar to threatened/spontaneous/missed abortion
  - pathological diagnosis often made after D&C

Investigations
- quantitative β-hCG levels (tumor marker) abnormally high for gestational age
- U/S findings:
  - if complete: no fetus (classic "snow storm" due to swelling of villi)
  - if partial: molar degeneration of placenta ± fetal anomalies, multiple echogenic regions corresponding to hydropic villi, and focal intrauterine hemorrhage
- CXR (may show metastatic lesions)
- features of molar pregnancies at high risk of developing persistent GTN post-evacuation:
  - local uterine invasion as high as 31%
  - β-hCG >100,000 IU/L
  - excessive uterine size
  - prominent theca-lutein cysts

Treatment
- suction D&C with sharp curettage and oxytocin
- Rhogam® if Rh negative
- consider hysterectomy (if patient no longer desires fertility)
- prophylactic chemotherapy of no proven benefit
- chemotherapy for GTN if develops after evacuation

Follow-up
- contraception required to avoid pregnancy during entire follow-up period
- serial β-hCGs (as tumor marker) every wk until negative x 3 (usually takes several wk), then monthly for 6-12 mo prior to trying to conceive again
- increase or plateau of β-hCG indicates GTN → patient needs chemotherapy

GTN Diagnosis
- β-hCG plateau: <10% drop in β-hCG over four values in 3 wk (e.g. days 1, 7, 14, and 21) OR
- β-hCG rise >20% in any two values over two wk or longer (e.g. measure at days 1, 7, 14) OR
- β-hCG persistently elevated >6 mo OR
- Metastases on workup
**GTN (MALIGNANT GTD)**

**Invasive Mole or Persistent GTN**
- diagnosis made by rising or plateau in β-hCG, development of metastases following treatment of documented molar pregnancy
- histology: molar tissue from D&C
- metastases are rare (4%)

**Choriocarcinoma**
- often present with symptoms from metastases
- highly anaplastic, highly vascular
- no chorionic villi, elements of syncytiotrophoblast, and cytotrophoblast
- may follow molar pregnancy, abortion, ectopic, or normal pregnancy

**Placental-site Trophoblastic Tumor**
- rare aggressive form of GTN
- abnormal growth of intermediate trophoblastic cells
- low β-hCG, production of human placental lactogen (hPL), relatively insensitive to chemotherapy

**CLASSIFICATION of GTN**
- non-metastatic
  - ~15% of patients after molar evacuation
  - may present with abnormal bleeding
  - all have rising or plateau of β-hCG
  - negative metastases on staging investigations
- metastatic
  - 4% patients after treatment of complete molar pregnancy
  - metastasis more common with choriocarcinoma which tends toward early vascular invasion and widespread dissemination
  - if signs or symptoms suggest hematogenous spread, do not biopsy (they bleed)
    - lungs (80%): cough, hemoptysis, CXR lesion(s)
    - vagina (30%): vaginal bleeding, "blue lesions" on speculum exam
    - pelvis (20%): rectal bleeding (if invades bowel), U/S lesion(s)
    - liver (10%): elevated LFTs, U/S or CT findings
    - brain (10%): headaches, dizziness, seizure (symptoms of space-occupying lesion), CT/MRI findings
  - highly vascular tumor → bleeding → anemia
  - all have rising or plateau of β-hCG
  - classification of metastatic GTN
    - divided into good prognosis and bad prognosis
      - long duration (>4 mo from antecedent pregnancy)
      - high pre-treatment β-hCG titre: >100,000 IU/24 h urine or >40,000 IU/L of blood
      - brain or liver metastases
      - prior chemotherapy
      - metastatic disease following term pregnancy
    - good prognosis characterized by the absence of each of these features

**Investigations – For Staging**
- blood work: CBC, electrolytes, creatinine, β-hCG, TSH, LFTs
- imaging: CXR, U/S pelvis, CT abdo/pelvis, CT brain
- if suspect brain metastasis but CT brain negative, consider lumbar puncture for CSF β-hCG
  - ratio of plasma β-hCG:CSF β-hCG <60 indicates metastases

Follow-up (for GTN)
- contraception for all stages to avoid pregnancy during entire follow-up period
- stage I, II, III
  - weekly β-hCG until 3 consecutive normal results
  - then monthly x 12 mo
- stage IV
  - weekly β-hCG until 3 consecutive normal results
  - then monthly x 24 mo

Common Medications

Table 27. Common Medications

<table>
<thead>
<tr>
<th>Drug Name (Brand Name)</th>
<th>Action</th>
<th>Dosing Schedule</th>
<th>Indications</th>
<th>Side Effects (S/E), Contraindications (C/I), Drug Interactions (D/I)</th>
</tr>
</thead>
<tbody>
<tr>
<td>acyclovir (Zovirax®)</td>
<td>Antiviral; inhibits DNA synthesis and viral replication</td>
<td>First Episode: 400 mg PO tid x 7-10 d Recurrence: 400 mg PO tid x 5 d</td>
<td>Genital herpes</td>
<td>S/E: headache, GI upset D/I: zidovudine, probenecid</td>
</tr>
<tr>
<td>bromocriptine (Parlodel®)</td>
<td>Dopaminomimetic Agonist at D2R Antagonist at D1R Acts directly on anterior pituitary cells to inhibit synthesis and release of prolactin</td>
<td>Initial: 1.25-2.5 mg PO qhs with food Then: increase by 2.5 mg every 2-7 d as needed until optimal therapeutic response Usual Range: 1.5-15 mg OD For IVF: Initial: 1.25 mg/d PO between days 4-6 of follicular phase Then: 2.5 mg/d until 3 d after onset menstruation</td>
<td>Galactorrhea + amenorrhea Z+ to hyperprolactinemia Prolactin-dependent menstrual disorders and infertility Prolactin-secreting adenomas (microadenomas, prior to surgery of macroadenomas) IVF</td>
<td>S/E: N/V, headache, postural hypotension, somnolence C/I: uncontrolled HTN, pregnancy-induced HTN, CAD, breastfeeding D/I: domperidone, macrolides, octreotide</td>
</tr>
<tr>
<td>clomiphene citrate (Clomid®)</td>
<td>Increases output of pituitary gonadotropins which induces ovulation</td>
<td>50 mg OD x 5 d Try 100 mg or 160 mg OD if ineffective 3 courses = adequate trial</td>
<td>Patients with persistent ovulatory dysfunction (e.g. amenorrhea, PCOS) who desire pregnancy</td>
<td>S/E: Common – hot flashes, abdominal discomfort, exaggerated cyclic ovarian enlargement, accentuation of Mittelschmerz Rare – ovarian hyperstimulation syndrome, multiple pregnancy, visual blurring, birth defects C/I: pregnancy, liver disease, hormone-dependent tumors, ovarian cyst, undiagnosed vaginal bleeding D/I: warfarin, carbamazepine, cyclosporine, tacrolimus, anti-hypertensives</td>
</tr>
<tr>
<td>clotrimazole (Lotrimin®)</td>
<td>Antifungal; disrupt fungal cell membrane</td>
<td>Tablet: 100 mg/d intravaginally x 7 d or 200 mg/d x 3 d or 500 mg x 1 dose Cream (1 or 2%): 1 applicator intravaginally qhs x 3-7 d Topical: apply bid x 7 d</td>
<td>Vulvovaginal candidiasis</td>
<td>S/E: vulvar/vaginal burning</td>
</tr>
<tr>
<td>danazol (Danocrine®)</td>
<td>Synthetic steroid that inhibits pituitary gonadotropin output and ovarian steroid synthesis Has mild androgenic properties</td>
<td>200-800 mg in 2-3 divided doses Used for 3-6 mo Biannual hepatic U/S required if &gt;6 mo use</td>
<td>Endometriosis 1° menorrhagia/DUB</td>
<td>S/E: weight gain, acne, mild hirsutism, hepatic dysfunction C/I: pregnancy, undiagnosed vaginal bleeding, breastfeeding, severely impaired renal/hepatic/cardiac function, porphyria, genital neoplasia, thromboembolic disease D/I: warfarin, carbamazepine, cyclosporine, tacrolimus, anti-hypertensives</td>
</tr>
</tbody>
</table>

<tr>
<td>doxycycline</td>
<td>Tetracycline derivative; inhibit protein synthesis</td>
<td>100 mg PO bid x ≥ 7 d</td>
<td>Chlamydia, gonococcal infection, syphilis</td>
<td>S/E: GI upset, hepatotoxicity C/I: pregnancy, severe hepatic dysfunction D/I: warfarin, digoxin</td>
</tr>
<tr>
<td>fluconazole (Diflucan&lt;sup&gt;®&lt;/sup&gt;)</td>
<td>Antifungal; disrupt fungal cell membrane</td>
<td>150 mg PO x 1 dose</td>
<td>Vulvovaginal candidiasis unresponsive to clotrimazole</td>
<td>S/E: headache, rash, N/V, abdominal pain, diarrhea D/I: terfenadine, cisapride, astemizole, hydrochlorothiazide, phenytoin, warfarin, rifampin</td>
</tr>
<tr>
<td>leuprolide (Lupron&lt;sup&gt;®&lt;/sup&gt;)</td>
<td>Synthetic GnRH analog Induces reversible hypoestrogenic state</td>
<td>3.75 mg IM q1mo or 11.25 mg IM q3mo Usually ≤ 6 mo, check bone density if &gt; 6 mo Retreatment with Lupron&lt;sup&gt;®&lt;/sup&gt; alone not recommended because of effects on bone density</td>
<td>Endometriosis Leiomyomata DUB Precocious puberty</td>
<td>S/E: hot flashes, sweats, headache, vaginitis, reduction in bone density, acne, GI upset C/I: pregnancy, undiagnosed vaginal bleeding, breastfeeding</td>
</tr>
<tr>
<td>menotropin (Pergonal&lt;sup&gt;®&lt;/sup&gt;)</td>
<td>Human gonadotropin with FSH and LH effects; induce ovulation and stimulate ovarian follicle development</td>
<td>75-150 U of FSH and LH IM OD x 7-12 d, then 10,000 U hCG one day after last dose</td>
<td>Infertility</td>
<td>S/E: bloating, irritation at injection site, abdominal/pelvic pain, headache, N/V, multiple pregnancy C/I: primary ovarian failure, intracranial lesion (e.g. pituitary tumor), uncontrolled thyroid/adrenal dysfunction, ovarian cyst (not PCOS), pregnancy, undiagnosed uterine bleeding</td>
</tr>
<tr>
<td>metronidazole (Flagyl&lt;sup&gt;®&lt;/sup&gt;)</td>
<td>Bactericidal; forms toxic metabolites which damage bacterial DNA</td>
<td>2 g PO x 1 dose or 500 mg PO bid x 7 d</td>
<td>Bacterial vaginosis, trichomonas vaginitis</td>
<td>S/E: headache, diziness, N/V, diaphoresis, disulfiram-like reaction (flushing, tachycardia, V/V) C/I: pregnancy (1st trimester) D/I: cisapride, warfarin, cimetidine, lithium, alcohol, amidotride, milk thistle, carbamazepine</td>
</tr>
<tr>
<td>oxybutinin (Ditropan&lt;sup&gt;®&lt;/sup&gt;)</td>
<td>Anticholinergic – relaxes bladder smooth muscle, inhibits involuntary detrusor contraction</td>
<td>5 or 10 mg/d PO May increase doses by 5 mg weekly to a max of 30 mg/d</td>
<td>Overactive bladder (urge incontinence)</td>
<td>S/E: dry mouth/eyes, constipation, palpitations, urinary retention, diziness, headache C/I: glaucoma, GI liens, severe colitis, obstructive urethra, use with caution if impaired hepatic/renal function</td>
</tr>
<tr>
<td>tolterodine (Detrol&lt;sup&gt;®&lt;/sup&gt;)</td>
<td>Anticholinergic</td>
<td>1-2 mg PO bid</td>
<td>Overactive bladder (urge incontinence)</td>
<td>S/E: anaphylaxis, psychosis, tachycardia, dry mouth/eyes, headache, constipation, urinary retention, chest pain, abdominal pain C/I: glaucoma, gastric/urinary retention, use with caution if impaired hepatic/renal function</td>
</tr>
<tr>
<td>tranexamic acid (Cyklokapron&lt;sup&gt;®&lt;/sup&gt;)</td>
<td>Anti-fibrinolytic, reversibly inhibits plasminogen activation</td>
<td>1.5 g tid-qid for first 4 d of cycle Max 4 g/d Ophthalmic check if used for several wk</td>
<td>Menorrhagia</td>
<td>S/E: N/V, diziness, rare cases of thrombosis, abdominal pain, MSK pain C/I: thromboembolic disease, acquired disturbances of color vision, subarachnoid hemorrhage, age &lt;15 yr</td>
</tr>
<tr>
<td>urofollitropin (Metrodin&lt;sup&gt;®&lt;/sup&gt;)</td>
<td>FSH</td>
<td>75 U/d SC x 7-12d</td>
<td>Ovulation induction in PCOS</td>
<td>S/E: ovarian enlargement or cysts, edema and pain at injection site, arterial thromboembolism, fever, abdominal pain, headache, multiple pregnancy C/I: primary ovarian failure, intracranial lesion (e.g. pituitary tumor), uncontrolled thyroid/adrenal dysfunction, ovarian cyst (not PCOS), pregnancy, abnormal uterine bleeding</td>
</tr>
<tr>
<td>combined oral contraceptive pill (OCP)</td>
<td>Ovulatory suppression by inhibiting LH and FSH Decidualization of endometrium Thickening of cervical mucus to prevent sperm penetration</td>
<td></td>
<td>Contraception Disorders of menstruation</td>
<td>See Tables 8-12</td>
</tr>
<tr>
<td>intrauterine device (IUD)</td>
<td>Copper IUD: mild foreign body reaction in endometrium which is toxic to sperm and alters sperm motility Progestosterone-releasing IUD: decidualization of endometrium and thickening of cervical mucus, may suppress ovulation</td>
<td>Contraceptive effects last 5 yr</td>
<td>Same as above</td>
<td>See Table 8-12</td>

**Basics of Hematology**

- over $10^{11}$ blood cells are produced daily
- sites of hematopoiesis in adults: pelvis, sternum, vertebral bodies
- lifespan of mature cells in blood
  - erythrocytes (120 d), neutrophils (~1 d), platelets (10 d), lymphocytes (varies – memory cells persist for years)
- role of lymphoid organs
  - spleen: part of reticuloendothelial system, removes aged RBCs, removes antibody-coated bacteria/cells, site of antibody production
  - thymus: site of T-cell maturation, involutes with age
  - lymph nodes: sites of B and T-cell activation (adaptive immune response)

---

**Hematopoietic Stem Cell**

- **Megakaryocyte/erythrocyte precursor**
  - Megakaryoblast
  - Proerythroblast
  - Polychromatic erythroblast
  - Platelets
  - Erythrocyte

- **Myeloid precursor**
  - Monoblast
  - Monoerythroblast
  - Macrophage

### Complete Blood Count

#### Table 1. Common Terms Found on CBC

<table>
<thead>
<tr>
<th>Test</th>
<th>Definition</th>
<th>Normal Values*</th>
</tr>
</thead>
<tbody>
<tr>
<td>Red Blood Cell (RBC) Count</td>
<td>The number of RBCs per volume of blood</td>
<td>4.2-6.9 x 10^6/mm³</td>
</tr>
<tr>
<td>Hemoglobin (Hb)</td>
<td>Amount of oxygen-carrying protein in the blood</td>
<td>13-18 g/dL (male)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>12-16 g/dL (female)</td>
</tr>
<tr>
<td>Hematocrit (Hct)</td>
<td>Percentage of a given volume of whole blood occupied by packed RBCs</td>
<td>45%-62% (male)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>37%-48% (female)</td>
</tr>
<tr>
<td>Mean Corpuscular Volume (MCV)</td>
<td>Measurement of size of RBCs</td>
<td>80-100 µm³</td>
</tr>
<tr>
<td>Mean Corpuscular Hb (MCH)</td>
<td>Amount of oxygen-carrying Hb inside RBCs</td>
<td>27-32 pg/cell</td>
</tr>
<tr>
<td>Mean Corpuscular Hb Concentration (MCHC)</td>
<td>Average concentration of Hb inside RBCs</td>
<td>32%-36%</td>
</tr>
<tr>
<td>RBC Distribution Width (RDW)</td>
<td>Measurement of variance in RBC size</td>
<td>11.0%-15.0%</td>
</tr>
<tr>
<td>White Blood Cell (WBC) Count</td>
<td>The number of WBCs per volume of blood</td>
<td>4,300-10,800/mm³</td>
</tr>
<tr>
<td>WBC Differential</td>
<td>Includes neutrophils, eosinophils, basophils, lymphocytes, and monocytes</td>
<td></td>
</tr>
<tr>
<td>Platelet Count</td>
<td>The number of platelets per volume of blood</td>
<td>150,000-400,000/mm³</td>
</tr>
<tr>
<td>Mean Platelet Volume (MPV)</td>
<td>Measurement of platelet size</td>
<td></td>
</tr>
<tr>
<td>Reticulocytes</td>
<td>Immature RBCs that contain no nucleus but have residual RNA</td>
<td>Normally make up 1% of total RBC count</td>
</tr>
</tbody>
</table>

*Normal values may vary depending on site and age

#### Approach to Interpreting a CBC

1. Consider values in the context of individual's baseline
   - up to 5% of population without disease may have values outside “normal” range
   - an individual may display a clinically significant change from their baseline without violating “normal” reference range
2. Is one cell line affected or are several?
   - if all lines are low: pancytopenia (see Pancytopenia, H8)
   - if RBCs and platelets are low: consider a MAHA (see H22)
   - if single cell line affected: see corresponding section in Common Presenting Problems, H6

#### Blood Film Interpretation

**RED BLOOD CELLS**

**Size**
- microcytic (MCV <80), normocytic (MCV = 80-100), macrocytic (MCV >100)
- anisocytosis: RBCs with increased variability in size (increased RDW)
  - iron deficiency anemia, hemolytic anemias, myelofibrosis, blood transfusion

**Color**
- hypochromic: increase in size of central pallor (normal = less than 1/3 of RBC diameter)
  - iron deficiency anemia, anemia of chronic inflammation, sideroblastic anemia
- polychromasia: increased reticulocytes (pinkish-blue cells)
  - increased RBC production by bone marrow

**Shape**
- poikilocytosis: increased proportion of RBCs of abnormal shape
  - iron deficiency anemia, myelofibrosis
Table 2. Common Erythrocyte Shapes

<table>
<thead>
<tr>
<th>Shape</th>
<th>Definition</th>
<th>Associated Conditions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Discocyte</td>
<td>Biconcave disc</td>
<td>Normal RBC</td>
</tr>
<tr>
<td>Spherocyte</td>
<td>Spherical RBC (due to loss of membrane)</td>
<td>Hereditary spherocytosis, immune hemolytic anemia, post-transfusion</td>
</tr>
<tr>
<td>Elliptocyte/Ovalocyte</td>
<td>Oval-shaped, elongated RBCs</td>
<td>Hereditary elliptocytosis, megaloblastic anemia, myelofibrosis, iron-deficiency, MDS</td>
</tr>
<tr>
<td></td>
<td>• Elliptocytes: the RBC long axis is ≥2x the length of the short axis</td>
<td>(myelodysplastic syndrome)</td>
</tr>
<tr>
<td></td>
<td>• Ovalcytes: the RBC long axis is &lt;2x the length of the short axis</td>
<td></td>
</tr>
<tr>
<td>Schistocyte (helmet cell)</td>
<td>Fragmented cells (due to traumatic disruption of membrane)</td>
<td>Microangiopathic hemolytic anemia (HUS/TTP, DIC, preeclampsia, HELLP, malignant HTN), vasculitis, glomerulonephritis, prosthetic heart valve</td>
</tr>
<tr>
<td>Sickle Cell</td>
<td>Sickle-shaped RBC (due to polymerization of hemoglobin S)</td>
<td>Sickle cell disorders: HbSC, HbSS</td>
</tr>
<tr>
<td>Codocyte (target cell)</td>
<td>“Bull’s eye” on dried film</td>
<td>Liver disease, hemoglobin SC, thalassemia, Fe deficiency, asplenia</td>
</tr>
<tr>
<td>Dacrocyte (teardrop cell)</td>
<td>Single pointed end, looks like a teardrop</td>
<td>Myelofibrosis, thalassemia major, megaloblastic anemia</td>
</tr>
<tr>
<td>Acanthocyte (spur cell)</td>
<td>Distorted RBC with irregularly distributed thorn-like projections (due to abnormal membrane lipids)</td>
<td>Severe liver disease (spur cell anemia), starvation/anoxia, post-splenectomy</td>
</tr>
<tr>
<td>Echinocyte (burr cell)</td>
<td>RBC with numerous regularly spaced, small spiny projections</td>
<td>Uremia, HUS, burns, cardiopulmonary bypass, post-transfusion, storage artifact</td>
</tr>
<tr>
<td>Rouleaux Formation</td>
<td>Aggregates of RBC resembling stacks of coins (due to increased plasma concentration of high molecular weight proteins)</td>
<td>Pregnancy: most common cause; due to physiological increase in fibrinogen, inflammatory conditions: due to polyclonal immunoglobulins Plasma cell dyscrasias: due to monoclonal paraproteinaemia, e.g. multiple myeloma, macroglobulinemia Storage artifact</td>
</tr>
</tbody>
</table>

DIC = disseminated intravascular coagulation; HELLP = hemolysis, elevated liver enzymes, and low platelet count; HUS = hemolytic uremic syndrome; TTP = thrombotic thrombocytopenic purpura.
Illustrations: Ayalah Hutchins and Merry Shiyu Wang 2012

Table 3. RBC Inclusions

<table>
<thead>
<tr>
<th>Inclusions</th>
<th>Definition</th>
<th>Associated Conditions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Nucleus</td>
<td>Present in erythroblasts (immature RBCs)</td>
<td>Hyperplastic erythropoiesis (seen in hypoxia, hemolytic anemia), BM infiltration disorders, MPNs (MF)</td>
</tr>
<tr>
<td>Heinz Bodies</td>
<td>Denatured and precipitated hemoglobin</td>
<td>G6PD deficiency (post-exposure to oxidant), thalassemia, unstable hemoglobins</td>
</tr>
<tr>
<td>Howell-Jolly Bodies</td>
<td>Small nuclear remnant resembling a pyknotic nucleus</td>
<td>Post-splenectomy, hyposplenism (sickle cell disease), neonates, megaloblastic anemia</td>
</tr>
<tr>
<td>Basophilic Stippling</td>
<td>Deep blue granulations indicating ribosome aggregation</td>
<td>Thalassemia, heavy metal (Pb, Zn, Ag, Hg) poisoning, megaloblastic anemia, hereditary (pyrimidine 5’nucleotidase deficiency)</td>
</tr>
<tr>
<td>Sideroblasts</td>
<td>Erythrocytes with Fe containing granules in the cytoplasm</td>
<td>Hereditary, idiopathic, drugs, hypothyroidism (see Sideroblastic Anemia, H16), myelodysplastic syndrome</td>
</tr>
</tbody>
</table>

BM = bone marrow; MF = myelofibrosis; MPN = myeloproliferative neoplasm.
Illustrations: Ayalah Hutchins and Merry Shiyu Wang 2012.
WHITE BLOOD CELLS
- lymphocytes: comprise 30-40% of WBCs; great variation in "normal" lymphocyte morphology
- neutrophils
  - normally only mature neutrophils (with 3-4 lobed nucleus) and band neutrophils (immediate precursor with horseshoe-shaped nucleus) are found in circulation
  - hypersegmented neutrophil: >5 lobes suggests megaloblastic process (B12 or folate deficiency)
  - left shift (increased granulocyte precursors)
    - seen in leukemoid reactions: acute infections, pregnancy, neonates, hypoxia, shock, myeloproliferative neoplasms (CML, MF)
- blasts
  - immature, undifferentiated precursors; associated with acute leukemia, MDS, G-CSF (growth factor that stimulates neutrophil production) use

PLATELETS
- small, purple, anuclear cell fragments

Table 4. Abnormal White Blood Cells on Film

<table>
<thead>
<tr>
<th>Appearance</th>
<th>Definition</th>
<th>Associated Conditions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reed-Sternberg Cell</td>
<td>Giant, multinucleated B-lymphocyte, only seen with bone marrow specimens</td>
<td>Primarily Hodgkin lymphoma, also seen in some non-Hodgkin lymphoma, CLL, and EBV infection</td>
</tr>
<tr>
<td>Smudge Cell</td>
<td>Lymphocytes damaged during blood film preparation indicating cell fragility</td>
<td>Chronic lymphocytic leukemia (CLL) and other lymphoproliferative disorders Pathognomonic in EBV infection</td>
</tr>
<tr>
<td>Auer Rod</td>
<td>Clumps of granular material that form long needles in the cytoplasm of myeloblasts</td>
<td>Pathognomonic for acute myeloid leukemia (AML)</td>
</tr>
</tbody>
</table>

EBV = Epstein-Barr virus
Illustrations: Ayalah Hutchins and Merry Shiyu Wang 2012

Bone Marrow Aspiration and Biopsy

- sites: posterior iliac crest, sternum
- analyses: most often done together; exception is in follow-up of conditions or diagnosis of CML where aspiration alone could suffice
  - aspiration: takes a fluid marrow sample for cellular morphology, flow cytometry, cytogenetics, molecular studies, microbiology (C&S, AFB, PCR)
  - biopsy: takes a sample of intact bone marrow to assess histology and immunohistochemistry

Indications
- unexplained CBC abnormalities
- diagnosis and evaluation of infiltrating cancers: plasma cell disorders, leukemias, solid tumors
- diagnosis and staging of lymphoma or solid tumors
- evaluate iron metabolism and stores (gold standard, but rarely done)
- evaluate suspected deposition and storage disease (e.g. amyloidosis, Gaucher's disease)
- evaluate fever of undetermined origin, suspected mycobacterial, fungal/parasitic infections, or granulomatous disease
- unexplained splenomegaly
- confirm normal bone marrow in potential allogenic hematopoietic cell donor

Contraindications
- absolute: untreated hemophilia, severe DIC, infection over skin site
- relative: platelet count <10, recent warfarin use with INR >2.0, liver disease with associated coagulopathy
- thrombocytopenia is not a contraindication; may need platelet transfusion prior to procedure
Common Presenting Problems

Anemia

Definition
- a decrease in red blood cell (RBC) mass that can be detected by hemoglobin (Hb) concentration, hematocrit (Hct), and RBC count
  - adult males: Hb <13 g/dL or Hct <0.41
  - adult females: Hb <12 g/dL or Hct <0.36

Low MCV (<80)
- Iron deficiency
- Thalassemia
- Anemia of chronic disease
- Sideroblastic anemia
- Lead poisoning

Normal MCV (80-100)

High MCV (>100)
- Megaloblastic
  - B12 deficiency
  - Folate deficiency
  - Drugs that impair DNA synthesis (methotrexate, sulfa, chemotherapy)
- Non-megaloblastic
  - Liver disease
  - Alcoholism
  - Reticulocytosis (see high reticulocyte, on left)
  - Hypothyroidism
  - Myelodysplasia

Low Hemoglobin

High reticulocyte
- Increased destruction (retics >2-3%)

Low reticulocyte
- Decreased production (retics <2%)

Hemolysis
- Inherited
  - Hemoglobinopathy (sickle cell disease, thalassemia, unstable Hb)
  - Membrane (spherocytic)
  - Metabolic (HMP shunt, glycolytic pathway)
- Acquired
  - Immune (Coombs positive, drug-related, cold agglutinin)
  - Infection (malaria)
  - Microniopagaphic hemolytic anemias (DIC, TTP, HUS, HELLP)
  - Oxidative/drug-related

Bleeding
- GI
- GU
- Other

Pancytopenia
- Aplastic anemia
- MDS
- Myelofibrosis
- Leukemia
- TB
- Amyloidosis, sarcoidosis
- Drugs (e.g. chemotherapy)

Non-pancytopenia
- Anemia of chronic disease
- Renal/liver disease

Low reticulocyte
- Decreased production (retics <2%)

HMP = hexose monophosphate

Figure 2. Approach to anemia – classification by size of RBC

Clinical Features
- history
  - symptoms of anemia: fatigue, malaise, weakness, dyspnea, decreased exercise tolerance, palpitations, headache, dizziness, tinnitus, syncope
  - acute vs. chronic, bleeding, systemic illness, diet, alcohol, family history
  - menstrual history: menorrhagia, menometrorrhagia, dysfunctional uterine bleeding
  - rule out pancytopenia (recurrent infection, mucosal bleeding/easy bruising)
- physical signs
  - HEENT: pallor in mucous membranes, palmar creases and conjunctiva at Hb <9.0 g/dL, ocular bruits at Hb <5.5 g/dL, angular cheilosis, jaundice
  - cardiac: tachycardia, orthostatic hypotension, systolic flow murmur, wide pulse pressure, signs of CHF
  - dermatologic: pallor in palmar skin creases at Hb <7.5 g/dL, jaundice (if due to hemolysis), nail changes, glossitis

Investigations
- rule out dilutional anemia (low Hb due to increased effective circulating volume)
- CBC with differential (MCV, RDW, RBC count)
- reticulocyte count – very useful to evaluate for blood cell production problems but must be corrected for anemia
- blood film
- rule out nutritional deficit, gastrointestinal and genitourinary disease in iron deficiency anemia
- additional laboratory investigations as indicated (see Microcytic Anemia, H13, Normocytic Anemia, H17, Hemolytic Anemia, H18, and Macrocytic Anemia, H24)

Erythrocytosis

Definition
- an increase in the number of RBCs: Hb >18.5 g/dL or Hct >52% (males); Hb >16.5 g/dL or Hct >47% (females and African males)

Etiology
- relative/spurious erythrocytosis (decreased plasma volume): diuretics, severe dehydration, burns, "stress" (Gaisböck's syndrome)
- absolute erythrocytosis
Table 5. Etiology of Erythrocytosis

<table>
<thead>
<tr>

</tbody>
</table>

Clinical Features
- secondary to high red cell mass and hyperviscosity
  - headache, dizziness, tinnitus, visual disturbances, hypertensive symptoms
  - symptoms of angina, congestive heart failure, aquagenic pruritus
  - thrombosis (venous or arterial) or bleeding (abnormal platelet function)
- physical findings
  - splenomegaly ± hepatomegaly, facial plethora/ruddy complexion (70%) and/or palms, gout

Investigations
- serum erythropoietin (EPO): increased EPO suggests autonomous production or hypoxia, and is used to rule out PV
  - search for tumor as source of EPO as indicated (e.g. abdominal U/S, CT head)
  - JAK-2 mutation analysis: positive in >96% of cases of PV
  - only send if low/normal EPO level
- ferritin (iron deficiency can mask the diagnosis)

Treatment
- if primary: see Polycythemia Vera, H41
- if secondary: treat underlying cause
  - O₂ for hypoxemia, CPAP for sleep apnea, surgery for EPO-secreting tumors
  - often cardiologists will not treat high HCT in cyanotic patients (or will have high threshold)

Thrombocytopenia

Definition
- platelet count <150,000/mm³

Clinical Features
- history: bleeding gums, epistaxis, bleeding post-surgical procedures, metronomorrhagia
- physical exam: bruising, petechiae, ecchymoses, non-palpable purpura
  - hemarthrosis and deep muscle hematomas are rarely initial signs in patients with primary hemostatic disorders
- see Disorders of Primary Hemostasis, H27, for complications

Investigations
- CBC and differential
- blood film
  - decreased production: other cell line abnormalities, blasts, hypersegmented PMNs, leukoerythroblastic changes
  - increased destruction: large platelets, schistocytes (seen in MAHA)
  - rule out platelet clumping
- workup for nutritional deficiencies: B₁₂, RBC folate
- PT/INR, aPTT and fibrinogen if DIC suspected
- LFTs

Treatments
- life threatening bleeding: platelet transfusion (repeat CBC 1 h post-transfusion to confirm an appropriate rise in counts)
- if secondary: treat underlying cause
- ITP: see Immune Thrombocytopenic Purpura, H27

Must rule out factitious thrombocytopenia: platelet clumping (secondary to EDTA antibodies from collection tube). This can be seen on blood film and confirmed by repeating in a citrated sample (i.e. using a sodium citrate tube to collect blood, rather than EDTA)

In hospitalized patients, drugs and infection account for the majority of cases of thrombocytopenia.
**Thrombocytopenia**

**Definition**
- platelet count >400,000/mm³
- primary thrombocytopenia: due to myeloproliferative neoplasms (e.g. CML, polycythemia vera [PV], primary myelofibrosis, essential thrombocytosis [ET]; rarely associated with MDS)
- reactive/secondary thrombocytopenia: acute phase reactant (e.g. surgery, inflammation, infection, trauma, bleeding, iron deficiency, neoplasms, ischemic injury); much more common than primary

**Clinical Features**
- history: trauma, surgery, splenectomy, infection, inflammation, bleeding, iron deficiency, prior diagnosis of chronic hematologic disorder, constitutional symptoms (malignancy)
- vasomotor symptoms: headache, visual disturbances, lightheadedness, atypical chest pain, acral dysesthesia, erythromelalgia, livedo reticularis, aquagenic pruritus
- clotting risk, bleeding risk (rare)
- physical exam: splenomegaly can be seen in myeloproliferative neoplasms (MPNs)

**Investigations**
- CBC, peripheral blood film, serum ferritin concentration
- non-specific markers of infection or inflammation (e.g. CRP, ESR, ferritin)
- JAK-2 PCR (mutation in ~50% of ET)
- if reactive process has been ruled out, bone marrow biopsy may be required to rule out MPN/MDS

**Treatment**
- primary: ASA ± cytoreductive agents
- secondary: treat underlying cause

---

**Pancytopenia**

**Definition**
- a decrease in all hematopoietic cell lines

**Clinical Features**
- anemia: fatigue
- leukopenia: recurrent infections
- thrombocytopenia: mucosal bleeding and ecchymoses

**Investigations**
- CBC, peripheral blood film, serum ferritin concentration
- non-specific markers of infection or inflammation (e.g. CRP, ESR, ferritin)
- JAK-2 PCR (mutation in ~50% of ET)
- if reactive process has been ruled out, bone marrow biopsy may be required to rule out MPN/MDS
Neutrophilia

Definition
• different guidelines, but absolute neutrophil count (ANC) >7.7 x 10^9/L

Etiology
• primary neutrophilia
  ▪ chronic myeloid leukemia (CML)
  ▪ other myeloproliferative disorders: PV, essential thrombocytosis (ET), myelofibrosis
  ▪ hereditary neutrophilia (autosomal dominant)
  ▪ chronic idiopathic neutrophilia in otherwise healthy patients
  ▪ leukocyte adhesion deficiency
• secondary neutrophilia
  ▪ smoking: most common cause of mild neutrophilia
  ▪ infection: leukocytosis with left shift ± toxic granulation, Döhle bodies (intra-cytoplasmic structures composed of agglutinated ribosomes)
  ▪ inflammation: e.g. rheumatoid arthritis (RA), IBD, chronic hepatitis, MI, PE, burns
  ▪ malignancy: hematologic (i.e. marrow invasion by tumor) and non-hematologic (especially large cell lung cancer)
  ▪ stress/exercise/epinephrine: movement of neutrophils from marginated pool into circulating pool
  ▪ medications: glucocorticoids, β-agonists, lithium

Clinical Features
• look for signs and symptoms of fever, inflammation, malignancy to determine appropriate further investigations
  ▪ including lymph nodes and organomegaly
• examine oral cavity, teeth, peri-rectal area, genitals, and skin for signs of infection

Investigations
• CBC and differential: mature neutrophils or bands >20% of total WBC suggests infection/inflammation
• blood film: Döhle bodies, toxic granulation, cytoplasmic vacuoles in infection
• review other blood counts
• may require bone marrow biopsy if MPN suspected

Treatment
• directed at underlying cause

Neutropenia

Definition
• mild: ANC 1,000-1,500/mm^3
• moderate: ANC 500-1,000/mm^3 (risk of infection starts to increase)
• severe: ANC <500/mm^3
• profound: ANC <100/mm^3 for >7 d
**Etiology**

**Table 6. Etiology of Neutropenia**

</tbody>
</table>

**Clinical Features**
- fever, chills (only if infection present)
- infection by endogenous bacteria (e.g. *S. aureus*, gram negatives from GI and GU tract)
- painful ulceration on skin, anus, mouth, and throat following colonization by opportunistic organisms
- avoid digital rectal exam

**Investigations**
- dependent on degree of neutropenia, history, and symptoms
- ranges from observation with frequent CBCs to bone marrow aspiration and biopsy

**Treatment**
- regular dental care: chronic gingivitis and recurrent stomatitis major sources of morbidity
- febrile neutropenia (see Infectious Diseases, ID46)
- in severe immune-mediated neutropenia, G-CSF may increase neutrophil counts
  - if no response to G-CSF, consider immunosuppression (e.g. steroids, cyclosporine, methotrexate)

**Lymphocytosis**

**Definition**
- absolute lymphocyte count >4 x 10⁹/L

**Etiology**
- infection
  - viral infections (majority); particularly mononucleosis
  - TB, pertussis, brucellosis, toxoplasmosis
  - physiologic response to stress (e.g. trauma, status epilepticus)
  - hypersensitivity (e.g. drugs, serum sickness)
  - autoimmune (e.g. rheumatoid arthritis)
  - neoplasm (e.g. ALL, CLL, lymphoma)

**Investigations**
- peripheral smear

**Treatment**
- treat underlying cause

**Lymphopenia**

**Definition**
- absolute lymphocyte count <1,500/mm³

**Etiology**
- idiopathic CD4+ lymphocytopenia
- radiation
- HIV/AIDS, hepatitis B, hepatitis C
- malignancy/chemotherapeutic agents
- malnutrition, alcoholism
- autoimmune disease (e.g. SLE)
Clinical Features
- opportunistic infections (see Infectious Diseases, ID46)

Treatment
- treat underlying cause
- treat opportunistic infections aggressively and consider antimicrobial prophylaxis
  (see Infectious Diseases, ID48)

Eosinophilia

Definition
- absolute eosinophil count >500/mm³

Etiology
- primary: due to clonal bone marrow disorder
  - if no primary etiology identified, classified as hypereosinophilic syndrome
    - 6 mo of eosinophilia with no other detectable causes (often with clonal molecular abnormality)
    - can involve heart, bone marrow, CNS
- secondary
  - most common causes are parasitic (usually helminth) infections and allergic reactions
  - less common causes:
    - polyarteritis nodosa, see Rheumatology, RH19
    - respiratory causes (asthma, eosinophilic pneumonia, Churg-Strauss)
    - cholesterol emboli
    - hematologic malignancy: see Chronic Myeloid Leukemia, H40 and Hodgkin Lymphoma, H45
    - adrenal insufficiency, see Endocrinology, E35
    - medications (penicillins)

Treatment
- treat underlying cause

Agranulocytosis

Definition
- severe depletion of granulocytes (neutrophils, eosinophils, basophils) from the blood and granulocyte precursors from bone marrow

Etiology
- associated with medications in 70% of cases: e.g. chemotherapy, clozapine, thionamides (antithyroid drugs), sulfasalazine, and ticlopidine
  - immune-mediated destruction of circulating granulocytes by drug-induced antibodies or direct toxic effects upon marrow granulocytic precursors

Clinical Features
- abrupt onset of fever, chills, weakness, and oropharyngeal ulcers

Prognosis
- high fatality without vigorous treatment

Investigations/Treatment
- discontinue offending drug
- pan-culture and screen for infection if patient is febrile (blood cultures x2, urine culture, and chest x-ray as minimum, initiate broad-spectrum antibiotics)
- consider bone marrow aspirate and biopsy if cause unclear
- consider G-CSF

Leukemoid Reactions

- blood findings resembling those seen in certain types of leukemia which reflect the response of healthy BM to cytokines released due to infection or trauma
- leukocytosis >50,000/mm³, marked left shift (myelocytes, metamyelocytes, bands in peripheral blood smear)

Etiology
- important to rule out CML
- differential diagnosis:
  - myeloid progenitors: pneumonia, other acute bacterial infections, intoxications, burns, malignant disease, severe hemorrhage or hemolysis
  - lymphoid progenitors: pertussis, TB, infectious mononucleosis
  - monocytic progenitors: TB
Approach to Lymphadenopathy

History
• constitutional/B-symptoms: seen in TB, lymphoma, other malignancies
• exposures: cats (cat scratch – *Bartonella henselae*), ticks (Lyme disease – *Borrelia burgdorferi*), high risk behaviors (HIV)
• joint pain/swelling, rashes (connective tissue disorder)
• pruritus (seen in Hodgkin lymphoma)
• medications (can cause serum sickness → lymphadenopathy)

Physical Exam
• basic assessment: occipital, preauricular, submandibular, cervical, supra-/infra-clavicular, axillary, epitrochlear, inguinal, popliteal nodes
  • characteristics of lymph nodes
  • look for signs of infection in regions which lymph nodes drain
• determine if lymphadenopathy is localized or generalized
• localized: typically reactive or neoplastic
  • cervical (bacterial/mycobacterial infections, ENT malignancies, metastatic cancer)
  • supraclavicular
    • right (mediastinal, bronchogenic, esophageal cancer)
    • left (gastric, gall bladder, pancreas, renal, testicular/ovarian cancer)
  • axillary (cat scratch fever, breast cancer, metastatic cancer)
  • epitrochlear (infections, sarcoidosis, lymphoma)
  • lower/inguinal (STDs, skin, cervix, vulva/penis, rectum/anus cancer)
• generalized: see Table 8
• thorough examination required to assess for systemic disease

Investigations
• CBC and differential, blood film
• ± tuberculin test, HIV RNA, RPR/VDRL, monospot/EBV serology, ANA, imaging as indicated
• if localized and no symptoms suggestive of malignancy, can observe 3-4 wk (if no resolution → biopsy)
• excisional biopsy is preferred as it preserves node architecture (essential for diagnosing lymphoma)
• in difficult to access areas (retroperitoneal, mediastinal/hilar) multiple core biopsies may be more practical/feasible
• FNA should NOT be used for diagnostic purposes in lymphoproliferative disease (use excisional biopsy instead)
  • helpful for recurrence of solid tumor malignancy

Table 7. Inflammatory vs. Neoplastic Lymph Nodes

</table>

The underlined conditions cause massive splenomegaly (spleen crosses midline or reaches pelvis)

### History
- constitutional symptoms, feeling of fullness in LUQ
- signs or symptoms of infection or malignancy
- history of liver disease, hemolytic anemia, or high-risk exposures

### Physical Exam
- jaundice, petechiae
- signs of chronic liver disease
- percussion (Castell's sign, Traube’s space, Nixon’s method) and palpation
- associated lymphadenopathy or hepatomegaly
- signs of CHF

### Investigations
- CBC and differential, blood film
- as indicated: liver enzymes/liver function tests, reticulocyte count, Monospot®, haptoglobin, LDH, infectious, and autoimmune workup
- imaging
  - ultrasound of abdomen/liver to rule out cirrhosis and portal vein thrombosis
  - echo for cardiac function
  - CT to rule out lymphoma

### Microcytic Anemia
- MCV <80 fL
- see Figure 2, Approach to Anemia, H6

### Iron Metabolism

#### Iron Intake (Dietary)
- average North American adult diet = 10-20 mg iron (Fe) daily
- absorption is 5-10% (0.5-2 mg/d); enhanced by citric acid, ascorbic acid (vitamin C) and reduced by polyphenols (e.g. in tea), phytate (e.g. in bran), dietary calcium, and soy protein
- males have positive Fe balance; up to 20% of menstruating females have negative Fe balance

### Causes of Splenomegaly
- CHINA
- Cirrhosis/Congestion (portal HTN)
- Hematological
- Infectious
- Neoplasm (malignant, non-malignant)
- Autoimmune

### Does This Adult Patient Have Splenomegaly?
- From The Rational Clinical Examination
- JAMA 2009; http://www.jamaevidence.com/content/3487289
- Study: Systematic review of articles assessing the sensitivity and specificity of clinical exam maneuvers for detecting splenomegaly.
- Results: On percussion, Nixon sign had a positive likelihood ratio (+LR) of 3.6 (95% CI 1.8-7.3) and a negative likelihood ratio (-LR) of 0.47 (95% CI 0.29-0.64). Percussion of Traube’s space had a +LR of 2.3 (95% CI 1.8-2.9) and -LR of 0.48 (95% CI 0.39-0.60), while Castell sign had a +LR of 1.2 (95% CI 0.98-1.6) and -LR of 0.45 (95% CI 0.19-1.1). On palpation, supine 1-handed palpation had a +LR of 6.5 (95% CI 3.1-1.5) and -LR of -0.41 (95% CI 0.30-0.57), while Middleton hooking maneuver had a +LR of 0.2 (95% CI 0.5-1.2) and -LR of 0.41 (95% CI 0.19-0.8). On palpation, supine 1-handed palpation had a +LR of 6.5 (95% CI 3.1-1.5) and -LR of 0.16 (95% CI 0.06-0.32).
- Conclusions: Palpation may have greater accuracy than percussion, but may be best when both are used in tandem. Specifically, Nixon sign and supine one-handed palpation are the most accurate, respectively.
Iron Indices

- bone marrow aspirate: gold standard test for iron stores (rarely done)
- serum ferritin: most important blood test for iron stores
  - decreased in iron deficiency anemia
  - elevated in:
    - infection, inflammation, malignancy
    - liver disease, hyperthyroidism, and iron overload
- serum iron: measure of all non-heme iron present in blood
  - varies significantly daily
  - virtually all serum iron is bound to transferrin, only a trace is free or complexed in ferritin
- TIBC: total amount of transferrin present in blood
  - normally, one third of TIBC is saturated with iron
  - high specificity for decreased iron, low sensitivity
- saturation: serum Fe divided by TIBC, expressed as a proportion or a percentage
  - low in iron deficiency anemia
- sTfR
  - reflects the availability of iron at the tissue level
  - the transferrin receptor is expressed on the surface of erythroblasts and is responsible for iron uptake – some is cleaved off and is present in circulation as sTfR
  - in iron deficient states more transferrin receptor is expressed on erythroblasts leading to an increase in sTfR
  - low in reduced erythropoiesis and iron overload
  - useful in determining iron deficiency in the setting of chronic inflammatory disorders (see Iron Deficiency Anemia, H15)

Iron Absorption and Transport

- dietary iron is absorbed in the duodenum (impaired by IBD, celiac disease, etc.)
- in circulation the majority of non-heme iron is bound to transferrin which transfers iron from enterocytes and storage pool sites (macrophages of the reticuloendothelial system and hepatocytes) to RBC precursors in the bone marrow

Iron Levels

- hepcidin that regulates systemic iron levels
  - a hormone produced by hepatocytes
  - binds to iron exporter ferroportin on duodenal enterocytes and reticuloendothelial cells, and induces its degradation thereby inhibiting iron export into the circulation
  - hepcidin production is increased in states of inflammation (thereby mediating anemia of chronic inflammation) or iron overload, and decreased in states where erythropoiesis is increased (e.g. hemolysis) or oxygen tension is low

Iron Storage

- ferritin
  - ferric iron (Fe$^{3+}$) complexed to a protein called apoferritin (hepatocytes are main ferritin storage site)
  - small quantities are present in plasma in equilibrium with intracellular ferritin
  - also an acute phase reactant – can be spuriously elevated despite low Fe stores in response to a stressor
- hemosiderin
  - aggregates or crystals of ferritin with the apoferritin partially removed
  - macrophage-monocyte system is main source of hemosiderin storage

Figure 5. Iron metabolism
Iron Deficiency Anemia

- see *Pediatrics*, P47
- most common cause of anemia in North America

Etiology
- increased demand
  - increased physiological need for iron in the body (e.g. pregnancy)
  - decreased supply: dietary deficiencies (rarely the only etiology)
    - cow’s milk (infant diet)
    - “tea and toast” diet (elderly)
    - absorption imbalances
    - post-gastrectomy
    - malabsorption (IBD of duodenum, celiac disease, autoimmune atrophic gastritis)
- increased losses
  - obvious causes: menorrhagia, abnormal uterine bleeding, frank GI bleed
  - occult: peptic ulcer disease, GI cancer
  - hemolysis
    - intravascular (e.g. PNH, cardiac valve RBC fragmentation)
    - extravascular (e.g. immune hemolytic anemias)

Clinical Features
- iron deficiency may cause fatigue before clinical anemia develops
- signs/symptoms of anemia: see *Anemia*, H6
- brittle hair, nail changes (brittle, koilonychia)
- Plummer-Vinson syndrome: dysphagia (esophageal webs), glossitis, angular stomatitis (inflammation and fissuring at the corners of the mouth)
- pica (appetite for non-food substances e.g. ice, paint, dirt)

Investigations
- iron indices, including soluble transferrin receptor
  - low ferritin (<45 µg/L) is diagnostic of iron deficiency
  - ferritin is an acute phase reactant and is elevated in the setting of inflammatory conditions and liver disease; serum ferritin <100 µg/L in these settings is suggestive of iron deficiency, necessitating further workup (Figure 6)
- peripheral blood film
  - hypochromic microcytosis: RBCs have low Hb levels due to lack of iron
  - pencil forms, anisocytosis
  - target cells (thin)
- bone marrow (gold standard but rarely done)
  - iron stain (Prussian blue) shows decreased iron in macrophages and in erythroid precursors (sideroblasts)
  - intermediate and late erythroblasts show micronormoblastic maturation

Table 11. The Utility of Ferritin in the Diagnosis of Iron Deficiency Anemia

<td>41.47</td>
</tr>
</tbody>
</table>

*Am J Med 1990;88:205-209*

Patient with microcytic anemia

- Ferritin ≤45 µg/ml
  - Iron deficiency anemia
  - Assess other iron indices
  - ↑ TIBC, ↓ serum Fe, ↓ saturation

- Ferritin 46-99 µg/ml
  - Any other result:
    - Order sTfR
    - ↑ TIBC, ↑ serum Fe, ↑ saturation

- Ferritin ≥100 µg/ml
  - NO iron deficiency anemia
  - ↓ TIBC, ↓ serum Fe, ↓ saturation
  - ↓ sTfR

Figure 6. Approach to interpreting iron indices

Adapted from: *Am Fam Physician* 2007;75:671-678

Treatment
- treat underlying cause
- supplementation
  - oral (tablets, syrup)
    - ferrous sulphate 325 mg tid, ferrous gluconate 300 mg tid, or ferrous fumarate 300 mg tid
    - supplement until anemia corrects, then continue for 3+ mo until serum ferritin returns to normal
    - oral iron should be taken with citrus juice to enhance absorption
  - IV (iron sucrose or dextran) can be used if patient cannot tolerate or absorb oral iron

Plummer-Vinson Syndrome Triad
- Dysphagia (esophageal)
- Glossitis
- Iron deficiency anemia
• monitoring response
  ▪ reticulocyte count will begin to increase after one wk
  ▪ Hb normalizes by 10 g/L per wk (if no blood loss)
  ▪ iron supplementation required for 4-6 mo to replenish stores

### Anemia of Chronic Inflammation

**Etiology**
- infection, malignancy, inflammatory and rheumatologic disease, chronic renal and liver disease, endocrine disorders (e.g. DM, hypothyroidism, hypogonadism, hypopituitarism)

**Pathophysiology**
- an anemia of underproduction due to impaired iron utilization (hepcidin is a key regulatory peptide)
  ▪ enterocyte trapping of iron → increased hepcidin inhibits ferroportin (↓ iron into circulation)
  ▪ macrophage trapping of iron → reduced plasma iron levels making iron relatively unavailable for new hemoglobin synthesis
  ▪ marrow unresponsive to normal or slightly elevated EPO
- mild hemolytic component is often present
- RBC survival is modestly decreased

**Investigations**
- diagnosis of exclusion
- associated with elevation in acute phase reactants (ESR, CRP, fibrinogen)
- "classic" serum iron indices (see Table 11)
  ▪ serum iron and TIBC low, % saturation normal
  ▪ serum ferritin is normal or increased
- anemia of chronic inflammation often co-exists with iron deficiency
- peripheral blood
  ▪ mild: usually normocytic and normochromic
  ▪ moderate: may be microcytic and normochromic
  ▪ severe: may be microcytic and hypochromic
- absolute reticulocyte count is frequently low, reflecting overall decrease in RBC production
- bone marrow
  ▪ normal or increased iron stores
  ▪ decreased or absent staining for iron in erythroid precursors

**Treatment**
- treat underlying disease
- only treat anemia in patients who can benefit from a higher hemoglobin
- IV iron if no benefit from PO iron
- erythropoietin indicated in chronic renal failure; not to be used if patient has concomitant curative solid tumor malignancy; ensure Hb target <110 g/L

### Sideroblastic Anemia

- uncommon compared to iron deficiency anemia or anemia of chronic inflammation

**Sideroblasts**
- erythrocytes with iron-containing (basophilic) granules in the cytoplasm
- "normal": granules are small, randomly spread in the cytoplasm
  ▪ found in healthy individuals
- "ring": iron deposits in mitochondria, forming a ring around the nucleus
  ▪ abnormal, large granules
  ▪ the hallmark of sideroblastic anemia

**Etiology**
- due to defects in heme biosynthesis in erythroid precursors
- hereditary (rare): X-linked; median survival 10 yr
- idiopathic (acquired)
  ▪ refractory anemia with ringed sideroblasts: a subtype of MDS (see Myelodysplastic Syndromes, H38)
  ▪ may be a preleukemic phenomenon (10% transform to AML)
- reversible
  ▪ drugs (isoniazid, chloramphenicol), alcohol, lead, copper deficiency, zinc toxicity, hypothyroidism
Clinical Features
- anemia symptoms (see Anemia, H6)
- hepatosplenomegaly, Fe⁺⁺ overload syndrome

Investigations
- serum iron indices
  - increased serum Fe⁺⁺, normal TIBC, increased ferritin, increased sTfR
- blood film/bone marrow biopsy
  - ringed sideroblasts (diagnostic hallmark)
  - RBCs are hypochromic; can be micro-, normo-, or macrocytic
  - anisocytosis, poikilocytosis, basophilic stippling

Treatment
- depends on etiology
  - X-linked: high dose pyridoxine (vitamin B6) in some cases
  - acquired: EPO and G-CSF
  - reversible: remove precipitating cause
- supportive transfusions for severe anemia

Lead Poisoning

Definition/Etiology
- blood lead levels greater than 80 µg/dL, possible symptomatology at 50 µg/dL.

Clinical Features
- identify source: consider occupational history, exposures history
- abdominal pain, constipation, irritability, difficulty concentrating

Treatment
- chelation therapy: dimercaprol and EDTA are first line agents

Thalassemia

- see Hemolytic Anemia – Thalassemia, H19

Normocytic Anemia

- MCV 80-100 fl.
- see Figure 2, Approach to Anemia, H6

Aplastic Anemia

Definition
- destruction of hematopoietic cells of the bone marrow leading to pancytopenia and hypocellular bone marrow

Epidemiology
- occurs at any age
- slightly more common in males

Etiology

Table 12. Etiology of Aplastic Anemia

<table>

</tr>
</tbody>
</table>

Clinical Features
- can present acutely or insidiously
- symptoms of anemia (see Anemia, H6), thrombocytopenia (see Thrombocytopenia, H7), and/or infection
- ± splenomegaly and lymphadenopathy (depending on the cause)
Investigations

- exclude other causes of pancytopenia (Figure 4)
- CBC
  - anemia or neutropenia or thrombocytopenia (any combination) ± pancytopenia
  - decreased reticulocytes (<1% of the total RBC count)
- blood film
  - decreased number of normal RBCs
- bone marrow
  - aplasia or hypoplasia of marrow cells with fat replacement
  - decreased cellularity

Treatment

- remove offending agents
- supportive care (red cell and platelet transfusions, antibiotics)
  - judicious use so as to not increase the risk of immune sensitization to blood products
- immunosuppression
  - anti-thymocyte globulin: 50-60% of patients respond
  - cyclosporine
- allogenic bone marrow transplant
- growth factors: e.g. Eltrombopag (TPO receptor agonist)

Hemolytic Anemia

- uncommon cause for anemia (<5% of cases) with many etiologies (>200)

Classification

- hereditary
  - abnormal membrane (spherocytosis, elliptocytosis)
  - abnormal enzymes (pyruvate kinase deficiency, G6PD deficiency)
  - abnormal hemoglobin synthesis (thalassemias, hemoglobinopathies)
- acquired
  - immune
    - autoimmune: warm vs. cold autoimmune hemolytic anemias (AIHA), see Table 15 Classification of AIHA, H22
    - alloimmune: hemolytic disease of the fetus/newborn
  - non-immune
    - MAHA: thrombus in blood vessels causes RBCs to be sheared
    - other causes: PNH, hypersplenism, Thrombocytopenia purpura (exertional hemolysis), infection (e.g. malaria), snake venoms, mechanical heart valves

- also classified as intravascular or extravascular
  - intravascular: G6PD deficiency, TTP, DIC, and PNH
  - extravascular: AIHA and hereditary spherocytosis

Clinical Features Specific to HA

- jaundice
- dark urine (hemoglobinuria, bilirubin)
- cholelithiasis (pigment stones)
- potential for an aplastic crisis (i.e. BM suppression in overwhelming infection)
- iron overload with extravascular hemolysis
- iron deficiency with intravascular hemolysis

Investigations

</tbody>
</table>

Tests Specific for Extravascular Hemolysis

- Direct Coombs test (direct antiglobulin test)
  - Detects IgG or complement on the surface of RBC
  - Add anti-IgG or anti-complement Ab to patient's RBCs; positive if agglutination
  - Indications: hemolytic disease of newborn, AIHA, hemolytic transfusion reaction

- Indirect Coombs test (indirect antiglobulin test)
  - Detects antibodies in serum that can recognize antigens on RBCs
  - Mix patient's serum + donor RBCs + Coombs serum (anti-human Ig Ab); positive if agglutination
  - Indications: cross-matching donor RBCs, atypical blood group, blood group Ab in pregnant women, AIHA
**Thalassemia**

**Definition**
- defects in production of the α or β chains of hemoglobin
  - resulting imbalance in globin chains leads to ineffective erythropoiesis and hemolysis in the spleen or BM
- clinical manifestations and treatment depends on specific gene and number of alleles affected
- common features
  - increasing severity with increasing number of alleles involved
  - hypochromic microcytic anemia
  - basophilic stippling, abnormally shaped RBCs on blood film

**Pathophysiology**
- defect may be in any of the Hb genes
  - normally 4 α genes in total; 2 on each copy of chromosome 16
  - normally 2 β genes in total; 1 on each copy of chromosome 11
  - fetal hemoglobin, HbF (α2γ2), switches to adult forms HbA (α2β2) and HbA2 (α2δ2) at 3-6 mo of life
  - HbA constitutes 97% of adult hemoglobin
  - HbA2 constitutes 3% of adult hemoglobin

**β-Thalassemia Minor (Thalassemia Trait)**

**Definition**
- defect in single allele of β gene (heterozygous)
- common in people of Mediterranean and Asian descent

**Clinical Features**
- None; a palpable spleen is very rare

**Investigations**
- Hb 100-140 g/L or 9-14 g/dL, MCV<70, normal Fe, normal RBC count
- peripheral blood film – microcytosis basophilic stippling
- Hb electrophoresis
  - specific: HbA2 increased to 3.5-5% (normal 1.5-3.5%)
  - non-specific: 50% have slight increase in HbF

**Treatment**
- no treatment required
- genetic counseling for patient and family

**β-Thalassemia Major**

**Definition**
- defect in both alleles of β gene (homozygous, autosomal recessive)

**Pathophysiology**
- ineffective chain synthesis leading to ineffective erythropoiesis, hemolysis of RBCs, and increase in HbF

**Clinical Features**
- initial presentation at age 6-12 mo when HbA normally replaces HbF
  - severe anemia, jaundice
  - iron overload
  - secondary to repeated transfusions and ineffective erythropoiesis
  - leads to iron-induced organ damage (liver, spleen, anterior pituitary, pancreas, and heart affected)
  - stunted growth and development (hypogonadal dwarf)
  - gross hepatosplenomegaly (due to extramedullary hematopoiesis)
  - radiologic changes (due to expanded marrow cavity) and extramedullary hematopoietic masses (erythroid tissue tumors)
  - skull x-ray has “hair-on-end” appearance
  - pathologic fractures common
- evidence of increased Hb catabolism (e.g. pigmented gallstones)
• death can result from
  ▪ untreated anemia (should transfuse)
  ▪ infection (should identify and treat early)
  ▪ iron overload: late complication secondary to repeated transfusions and ineffective
erthropoiesis

Investigations
• CBC: Hb 4-6 g/dL
• Hb electrophoresis
  ▪ HbA: 0-10% (normal >95%)
  ▪ HbA₂ >2.5%
  ▪ HbF: 90-100%

Treatment
• lifelong regular transfusions to suppress endogenous erythropoiesis
• iron chelation (e.g. deferoxamine, deferasirox, deferiprone) to prevent iron overload in organs
  and the formation of free radicals (which promote tissue damage and fibrosis)
• folic acid supplementation if not transfused
• allogenic bone marrow transplantation
• splenectomy (now performed less frequently)

β-Thalassemia Intermedia

Definition
• clinical diagnosis in patients whose clinical manifestations are too mild to be classified as
  thalassemia major, but too severe to be classified as thalassemia minor

Clinical Features
• wide variety of clinical phenotypes
• in most cases of TI, both β-globin genes affected
• three main mechanisms account for the milder phenotype compared to thalassemia major:
  (1) subnormal (vs. absent) beta-chain synthesis, (2) increased number of gamma chains, (3)
  coinheritance of alpha thalassemia
• complications more commonly seen in TI than thalassemia major include extramedullary
  hematopoiesis, leg ulcers, gallstones, thrombosis, and pulmonary HTN

α-Thalassemia

Definition
• defect(s) in α genes
• similar geographic distribution as β-thalassemia, but higher frequency among Asians and
  Africans

Clinical Features
• 1 defective α gene (aa/a-): clinically silent; normal Hb, normal MCV
• 2 defective α genes (cis: aa/– or trans: a-/a-): decreased MCV, normal Hb
  ▪ N.B. cis 2-gene deletion more common in Asia vs. trans 2-gene deletion more common in
    Africa – this leads to increased risk of fetal hydrops in offspring of Asian patients vs. African
    patients
• 3 defective α genes (a-/–): HbH (β4) disease; presents in adults, decreased MCV, decreased Hb,
splenomegaly
• 4 defective α genes (–/–): Hb Barts (γ4) disease (hydrops fetalis); usually incompatible with life

Investigations
• peripheral blood film – screen for HbH inclusion bodies with special stain
• Hb electrophoresis not diagnostic for α-thalassemia
• DNA analysis using α gene probes is the only way to confirm the diagnosis
• referral to genetic counselor prior to childbearing for patients with 2-gene cis deletion (or
  3-gene deletion), due to risk of fetal hydrops if partner also carries thalassemia trait

Treatment
• depends on degree of anemia
  ▪ 1 or 2 defective α genes: no treatment required
  ▪ HbH disease: similar to β-thalassemia intermedia
  ▪ HbBarts: intrauterine transfusion
Sickle Cell Disease

- see Pediatrics, P48

Definition
- sickling disorders arise due to a mutant β-globin chain, most commonly caused by a Glu → Val substitution at position 6 (chromosome 11) resulting in HbS variant, rather than HbA (normal adult Hb)
  - increased incidence of HbS allele with African or Mediterranean heritage (thought to be protective against malaria)
  - sickle cell disease occurs when an individual has two HbS genes (homozygous, HbSS) or one HbS gene + another mutant β-globin gene (compound heterozygote) – most commonly HbS-β-thal and HbSC disease

Pathophysiology
- at low pO2, deoxy HbS polymerizes leading to rigid crystal-like rods that distort membranes → ‘sickles’
- the pO2 level at which sickling occurs is related to the percentage of HbS present
  - heterozygotes (HbAS); sickling occurs at a pO2 of 40 mmHg
  - homozygotes (HbSS); sickling occurs at a pO2 of 80 mmHg
- sickling aggravated by acidemia, increased CO2, increased 2,3-DPG, fever, and osmolality
- fragile sickle cells then cause injury in two main ways:
  1. fragile sickle cells hemolyze (nitric oxide depletion)
  2. they also occlude small vessels (ischemia-reperfusion injury)

Clinical Features
- HbAS (sickle cell trait): patient will be asymptomatic except during extreme hypoxia or infection
  - increased risk of renal medullary carcinoma
- SCD-SS (HbSS)
  - chronic hemolytic anemia
  - jaundice in the first year of life
  - retarded growth and development ± skeletal changes
  - splenomegaly in childhood; splenic atrophy in adulthood
- SCD-SC often presents with acute pain episode
  1. aplastic crises
     - toxins and infections (especially parvovirus B19) transiently suppress bone marrow
  2. splenic sequestration crises
     - usually in children; significant pooling of blood in spleen resulting in acute Hb drop and shock
     - uncommon in adults due to asplenia from repeated infarction
  3. vaso-occlusive crises (infarction)
     - may affect various organs causing ischemia-reperfusion injury (especially in back, chest, abdomen, and extremities), fever, and leukocytosis
     - precipitated by infections, dehydration, rapid change in temperature, pregnancy, menses, and alcohol
  4. acute chest syndrome (see sidebar)
- SCD-SC (most common compound heterozygote)
  - 1:833 live births in African-Americans, common in West Africa
  - milder anemia than HbSS
  - similar complications as HbSS although typically milder and less frequent (exception is proliferative sickle retinopathy, glomerulonephritis, and avascular necrosis)
  - spleen not always atrophic in adults

Investigations
- sickle cell prep (detects sickling of RBCs under the microscope in response to O2 lowering agent): determines the presence of a HbS allele, but does not distinguish HbAS from HbSS
- Hb electrophoresis distinguishes HbAS, HbSS, HbSC, and other variants

<table>

<td><strong>HbAS</strong></td>
</tr>
<tr>
<td>CBC</td>
</tr>
<tr>
<td>Peripheral Blood</td>
</tr>
<tr>
<td>Hb Electrophoresis</td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

Treatment
- genetic counseling
- HbAS: no treatment required
- HbSC: treatment as per HbSS, but is dictated by symptom severity
• HbSS
  1. folic acid to prevent folate deficiency
  2. hydroxyurea to enhance production of HbF
     • mechanism of action: stops repression of Hb-γ chains and/or initiates differentiation of stem cells in which this gene is active
     • presence of HbF in the SS cells decreases polymerization and precipitation of HbS
  3. treatment of vaso-occlusive crisis
     • oxygen
     • hydration (reduces viscosity)
     • correct acidosis
     • analgesics/opiates
  • indication for exchange transfusion: acute chest syndrome, stroke, multi-organ failure, ICU admission
  • less routinely: antimicrobials for suspected infection
  4. prevention of crises
     • establish diagnosis
     • avoid conditions that promote sickling (hypoxia, acidosis, dehydration, fever)
     • vaccination in childhood (pneumococcus, meningococcus, H. influenzae b)
     • prophylactic penicillin (start age 3 mo and continue until at least 5 yr then continue on case by case basis)
     • good hygiene, nutrition, and social support
  5. screen for complications
     • regular blood work (CBC, reticulocytes, iron indices, BUN, LFTs, creatinine)
     • urinalysis annually (proteinuria, glomerulopathy)
     • transcranial doppler annually until 16 yr old (stroke prevention)
     • retinal examinations annually from 8 yr old (screen for retinopathy)
     • echocardiography starting at 10 yr old (screen for pulmonary HTN)

Autoimmune Hemolytic Anemia

Microangiopathic Hemolytic Anemia

Definition
• hemolytic anemia due to intravascular fragmentation of RBCs

Etiology
• see Thrombotic Thrombocytopenic Purpura and Hemolytic Uremic Syndrome, H30
• see Disseminated Intravascular Coagulation, H32
• eclampsia, HELLP syndrome, AFLP (see Obstetrics, OB17)
• malignant HTN
• vasculitis
• malfunctioning heart valves
• metastatic carcinoma
• drugs (calcineurin inhibitors, quinine, simvastatin)
• infections (severe CMV or meningococcus)
• catastrophic antiphospholipid antibody syndrome
Investigations
- blood film: evidence of hemolysis, schistocytes
- hemolytic workup
- urine: hemosiderinuria, hemoglobinuria

**Hereditary Spherocytosis**

- most common type of hereditary hemolytic anemia
- abnormality in RBC membrane proteins (e.g. spectrin)
  - spleen makes defective RBCs more spherocytotic (and more fragile) by membrane removal; also acts as site of RBC destruction
- autosomal dominant with variable penetrance

Investigations
- blood film shows spherocytes, increased osmotic fragility, molecular analysis for spectrin gene

Treatment
- in severe cases, splenectomy + vaccination against pneumococcus, meningococcus, and *H. influenzae* b (avoid in early childhood)

**Hereditary Elliptocytosis**

**Definition/Etiology**
- abnormality in spectrin interaction with other membrane proteins
- autosomal dominant
- 25-75% elliptocytes
- hemolysis is usually mild

Treatment
- immunizations; splenectomy for severe hemolysis

**Glucose-6-Phosphate Dehydrogenase Deficiency**

**Definition**
- deficiency in glucose-6-phosphate dehydrogenase (G6PD) leads to RBC sensitivity to oxidative stress due to a lack of reduced glutathione (GSH)

**Pathophysiology**
- X-linked recessive, prevalent in individuals of African, Asian, and Mediterranean descent

**Clinical Features**
- frequently presents as episodic hemolysis precipitated by
  - oxidative stress
  - drugs (e.g. sulfonamide, antimalarials, nitrofurantoin)
  - infection
  - food (fava beans)
- in neonates: can present as prolonged, pathologic neonatal jaundice

**Investigations**
- neonatal screening
- G6PD assay (may not be useful if result is normal)
  - should not be done in acute crisis when reticulocyte count is high (reticulocytes have high G6PD levels)
- blood film
  - Heinz bodies (granules in RBCs due to oxidized Hb); passage through spleen results in the generation of bite cells
  - may have features of intravascular hemolysis (e.g. RBC fragments)

**Treatment**
- folic acid
- stop offending drugs and avoid triggers
- transfusion in severe cases
Macrocytic Anemia

- MCV >100 fL
- see Figure 2, Approach to Anemia, H6

Vitamin B12 Deficiency

B12 (cobalamin) see Gastroenterology, G17 and Family Medicine – Nutrition, FM6
- binds to intrinsic factor (IF) secreted by gastric parietal cells
- absorbed in terminal ileum
- total body stores sufficient for 3-4 yr

Etiology

Table 17. Etiology of Vitamin B12 Deficiency

<table>
<thead>
<tr>
<th>Diet</th>
<th>Gastric</th>
<th>Intestinal Absorption</th>
<th>Genetic</th>
</tr>
</thead>
<tbody>
<tr>
<td>Strict vegan</td>

<tr>
<td></td>
<td></td>
<td>Drugs</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Neomycin, biguanides, PPI, N2O anesthesia</td>
<td></td>
</tr>
</tbody>
</table>

Pathophysiology of Pernicious Anemia

- auto-antibodies produced against gastric parietal cells leading to achlorhydria and lack of intrinsic factor secretion
- intrinsic factor is required to stabilize B12 as it passes through the bowel
- decreased intrinsic factor leads to decreased ileal absorption of B12
- may be associated with other autoimmune disorders (polyglandular endocrine insufficiency)
- F:M = 1.6:1; often >60 yr old

Clinical Features

- neurological
  - cerebral (common, reversible with B12 therapy)
  - confusion, delirium, dementia
  - cranial nerves (rare)
  - optic atrophy
  - cord (irreversible damage)
    - posterior columns: decreased vibration sense, proprioception, and 2-point discrimination
    - pyramidal tracts: spastic weakness, hyperactive reflexes
  - peripheral neuropathy (variable reversibility)
  - usually symmetrical, affecting lower limbs more than upper limbs

Investigations

- CBC, reticulocyte count
  - anemia often severe ± neutropenia ± thrombocytopenia
- MCV >110 fL
- low reticulocyte count relative to the degree of anemia (<2%)
- serum B12 and RBC folate
  - caution: low serum B12 leads to low RBC folate because of failure of folate polyglutamate synthesis in the absence of B12
  - alternatively, can measure urine metabolites (methylmalonate, homocysteine)
- blood film
  - oval macrocytes, hypersegmented neutrophils

Table 16. Comparison Between Megaloblastic and Non-Megaloblastic Macrocytic Anemia

<table>

<td>Schilling et al.</td>
<td>One study evaluated 1,000 μg of oral B12 compared to 1,000 μg IM B12 on the same dosing schedule. The other compared 2,000 μg daily oral B12 to 1,000 μg IM B12 on a less frequent dosing schedule. Neurological and hematomasal end points were evaluated.</td>
<td>90-94 mo.</td>
<td>No significant difference was observed between groups in either study.</td>
<td>No significant difference was observed between groups in either study.</td>
</tr>
</tbody>
</table>

Results: Meta-analysis was not attempted due to study heterogeneity. Both studies reported improvements in hematomasal and neurological end-points in both oral and IM groups. No significant difference was observed between groups in either study. Conclusions: Limited data suggesting high dose oral vitamin B12 (1,000-2,000 μg) is equivalent to IM vitamin B12 on the same or less frequent dosing schedule. This data is severely limited by small sample sizes and short follow-up periods. Insufficient numbers of patients with malabsorption conditions were included to generalize these results to the entire primary care population.
• bone marrow
  ▪ hypercellularity
  ▪ nuclear-cytoplasmic asynchrony in RBC precursors (less mature nuclei than expected from
    the development of the cytoplasm)
  ▪ bilirubin and LDH
  ▪ elevated unconjugated bilirubin and LDH due to breakdown of cells in BM
  ▪ Schilling test (see sidebar H24) to distinguish pernicious anemia from other causes
    ▪ anti-intrinsic factor antibody, anti-parietal cell antibody

Treatment
• vitamin B₁₂ 1,000 µg IM monthly for life or 1,000-1,200 µg PO daily if intestinal absorption intact
• less frequent, higher doses may be as effective (e.g. 1,000 µg IM q3mo)
• watch for hypokalemia and rebound thrombocytosis when treating severe megaloblastic anemia

Folate Deficiency

• uncommon in developed countries due to extensive dietary supplementation
• folate stores are depleted in 3-6 mo
• folate commonly found in green, leafy vegetables and fortified cereals

Etiology

Table 18. Etiology of Folate Deficiency

<table>
<thead>
<tr>
<th>Diet/Deficiency</th>

</tr>
</tbody>
</table>

Clinical Features
• mild jaundice due to hemolysis of RBCs secondary to ineffective hemoglobin synthesis
• glossitis and angular stomatitis
• melanin pigmentation (rare)
• purpura secondary to thrombocytopenia (rare)
• unlike B₁₂ deficiency, folate deficiency has no neurologic manifestations

Investigations
• similar to B₁₂ deficiency (CBC, reticulocytes, blood film, RBC folate, serum B₁₂)
• if decreased RBC folate, rule out B₁₂ deficiency as cause

Management
• folic acid 1-5 mg PO OD x 1-4 mo; then 1 mg PO OD maintenance if cause is not reversible

Hemostasis

Three Phases of Hemostasis

1. Primary Hemostasis
• goal is rapid cessation of bleeding; main effect is on mucocutaneous bleeding
• vessel injury results in collagen/subendothelial matrix exposure and release of
  vasoconstrictors
• blood flow is impeded and platelets come into contact with damaged vessel wall (Figure 11a)
  ▪ adhesion: platelets adhere to subendothelium via von Willebrand factor (vWF)
  ▪ activation: platelets are activated resulting in change of shape and release of ADP and
    thromboxane A₂
  ▪ aggregation: these factors further recruit and aggregate more platelets resulting in formation
    of localized hemostatic plug

2. Secondary Hemostasis
• platelet plug is reinforced by production of fibrin clot in secondary hemostasis (Figure 11b)
• extrinsic pathway
  ▪ initiation of coagulation in vivo
• intrinsic pathway
  ▪ amplification once coagulation has started

3. Fibrin Stabilization and Fibrinolysis (resolution)
• conversion from soluble to insoluble clot
• once healing initiated, clot dissolution (anticoagulant pathway)

## Disorders of Primary Hemostasis

### Definition
- inability to form an adequate platelet plug due to:
  - disorders of blood vessels
  - disorders of platelets: abnormal function/numbers
  - disorders of vWF

### Classification

<table>
<thead>
<tr>
<th>Low platelet count:</th>
<th>Normal platelet count:</th>

</tbody>
</table>

#### ACUTE (CHILD-TYPE) ITP
- see Pediatrics, P50

#### CHRONIC (ADULT-TYPE) ITP
- most common cause of isolated thrombocytopenia
- diagnosis of exclusion (i.e. isolated thrombocytopenia [platelets <100,000/mm³] and the absence of any obvious initiating and/or underlying cause)
Pathophysiology
- an acquired immune-mediated disorder with
  - anti-platelet antibodies bind to platelet surface → increased splenic destruction and clearance
  - impaired platelet production
  - helper T-cell and cytotoxic T-cell activation also implicated in platelet destruction

Clinical Presentation
- can present asymptomatic, minimal bruising, or serious bleed (GI bleed, skin and mucosal hemorrhage or intracranial hemorrhage), lethargy, fatigue

Investigations
- CBC and reticulocyte count: thrombocytopenia (request retic count if not an isolated thrombocytopenia)
- PT and aPTT: normal
- peripheral blood film: decreased platelets, giant platelets (to rule out platelet clumping)
- HIV, HCV (if risk factors are present)
- bone marrow aspirate and biopsy: increased number of megakaryocytes
  - recommended in patients >60 yr of age, pre-splenectomy or have failed multiple lines of ITP treatment, those with systemic symptoms, an abnormal blood film, and/or abnormal signs to rule out other causes of thrombocytopenia (e.g. myelodysplasia)

Treatment
- rarely indicated if platelets >30,000/mm³ unless active bleeding, trauma, or surgery

A. Emergency Treatment (active bleeding (CNS, GI, or GU) or in need of emergency surgery)
  - general measures: stop drugs reducing platelet function, control blood pressure, minimize trauma
  - corticosteroids: prednisone (1 mg/kg) or methylprednisolone (1 g/d x 3 d) or dexamethasone (40 mg PO x 4 d)
  - antifibrinolytic: tranexamic acid (1 g PO tid or 1 g IV q6h) if refractory bleeding
  - IVIg 1 g/kg/d x 2 doses, or 2 g/kg over 5 d
  - platelet transfusion: for life-threatening bleeding
  - emergency splenectomy: may be considered, vaccinations prior (pneumococcus, meningococcus, *H. influenzae* b)
  - management of intracranial bleeding: IV steroids, IVIg, platelets, emergency splenectomy, and then craniotomy; maintain Plt >100,000/mm³ for at least 7 wk post intracranial hemorrhage

B. Non-Urgent Treatment (platelet count <20,000-30,000/mm³ and no bleeding OR platelet count <50,000/mm³ and significant bleeding symptoms)
  - platelet transfusion does not work
  - 1st Line
    - corticosteroids (dexamethasone 40 mg/d x 4 wk or prednisone 1 mg/kg/d)
    - IVlg
    - anti-D: appropriate for Rh+ non-splenectomized patients, but can cause hemolysis (avoid if low Hb at baseline or if DAT is positive) (warning label now attached to this medication regarding risk of intravascular hemolysis)
  - 2nd Line
    - splenectomy (need vaccinations prior to splenectomy: pneumococcus, meningococcus, *H. influenzae* b)
    - immunosuppressants (azathioprine, cyclophosphamide)
    - rituximab
    - danazol, vincristine
    - thrombopoietin (TPO) receptor agonists (romiplostim, eltrombopag)

Prognosis
- ~20% will not attain a hemostatic platelet count after first and second line therapy
- fluctuating course
- overall relatively benign, mortality 1-2%, (2x higher mortality than the unaffected population)
- major concern is cerebral hemorrhage at Plt <5,000/mm³, although very rare
Heparin-Induced Thrombocytopenia

- heparin-induced thrombocytopenia: immune-mediated reaction following treatment with heparin leading to coagulation activation
- heparin-associated thrombocytopenia: transient thrombocytopenia following administration of heparin

Table 23. Heparin-Induced Thrombocytopenia (HIT) (Previously Known as HIT Type II)

| Pathophysiology | Immune mediated  
| Ab recognizes a complex of heparin and platelet factor 4 (PF4) leading to platelet activation via platelet Fc receptor and activation of coagulation system |
| Diagnosis | 50% reduction in platelets while on heparin within 5-15 wk of initiation |
| Onset of Decreased Platelets | 5-15 wk (if previously exposed to heparin, HIT can develop in hours) |
| Risk of Thrombosis | ~30% (25% of events are arterial) |
| Clinical Features | Bleeding complications uncommon  
| Venous thrombosis: DVT, PE, limb gangrene, cerebral sinus thrombosis  
| Arterial thrombosis: MI, stroke, acute limb ischemia, organ infarct (mesentery, kidney)  
| Heparin-induced skin necrosis (with LMWH)  
| Acute platelet activation syndromes: acute inflammatory reactions (e.g., fever/chills, flushing, etc.)  
| Transient global amnesia (rare) |
| Specific Tests | Pre-test clinical scoring models can help rule-out HIT: 4-Ts (see Table 24) and the HIT Expert Probability (HEP) score  
| 14C serotonin release assay (uses donor platelets with 14C serotonin and heparin with patient’s plasma)  
| ELISA for HIT-Ig (more sensitive, less specific than serotonin assay)  
| Ultrasound of lower limb veins for DVT |
| Management | Clinical suspicion of HIT should prompt discontinuation of heparin and LWMH (specific tests take several days)  
| Initiate anticoagulation with a non-heparin anticoagulant  
| e.g. argatroban, danaparoid, fondaparinux, bivalirudin unless there is a strong contraindication (duration of treatment at least 2-3 mo if no thrombotic event, and at least 3-6 mo if thrombotic event has occurred)  
| Warfarin should only be restarted when platelet count >100 x 10^9/L  
| Allergy band and alert in patient records |

von Willebrand Disease

Pathophysiology
- heterogeneous group of defects, usually mild in severity
- usually autosomal dominant (type 3 is autosomal recessive)
- qualitative or quantitative abnormality of vWF
  - vWF needed for platelet adhesion and acts as carrier for Factor VIII; abnormality of vWF can affect both primary and secondary hemostasis
  - vWF exists as a series of multimers ranging in size
    - largest multimers are most active in mediation of platelet adhesion, both large and small multimers complex with Factor VIII

Classification
- type 1: mild quantitative defect (decreased amount of vWF and proportional decrease in vWF activity) – 75% of cases
- type 2: qualitative defect (vWF activity disproportionally lower than quantity) – 20-25% of cases
- type 3: severe total quantitative defective (no vWF produced) – rare

Clinical Features
- mild
  - asymptomatic
  - mucosal and cutaneous bleeding, easy bruising, epistaxis, menorrhagia
- moderate to severe
  - as above but more severe, occasionally soft-tissue hematomas, petechiae (rare), GI bleeding, hemarthroses

Hematology Disorders of Prim. Hemostasis/Disorders of Secondary Hemostasis

Treatment

- desmopressin (DDAVP) is treatment of choice for type 1 vWD
  - causes release of vWF and Factor VIII from endothelial cells
  - variable efficacy depending on disease type; tachyphylaxis occurs
  - need good response before using with further bleeding
  - caution in children due to hyponatremia
- tranexamic acid (Cyklokapron, antifibrinolytic) to stabilize clot formation
- high-purity Factor VIII concentrate containing vWF (Hemate P) in select cases and type
  - frozen plasma (FP) is not useful
  - need to monitor vWF and factor VIII levels (very high factor VIII level can cause thrombosis)
- conjugated estrogens (increase vWF levels)

Prognosis

- may fluctuate, often improves during pregnancy, inflammation, and with age

Disorders of Secondary Hemostasis

Definition

- inability to form an adequate fibrin clot
  - disorders of clotting factors or co-factors
  - disorders of proteins associated with fibrinolysis
- characterized by delayed bleeding, deep muscular bleeding, spontaneous joint bleeding

Table 27. Classification of Secondary Hemostasis Disorders

</tbody>
</table>

Hemophilia A (Factor VIII Deficiency)

Pathophysiology

- X-linked recessive, 1/5,000 males
- mild (>5% of normal factor level), moderate (1-5%), severe (<1%)

Clinical Features

- see Table 20 – Signs and Symptoms of Disorders of Hemostasis, H26
- older patients may also have HIV or HCV from contaminated blood products

Investigations

- prolonged aPTT, normal INR (PT)
- decreased Factor VIII (<40% of normal)
- vWF usually normal or increased

Treatment

- desmopressin (DDAVP) in mild hemophilia A
- recombinant Factor VIII concentrate for
  - prophylaxis (2-3x/wk at home)
  - minor but not trivial bleeding (e.g. hemarthroses)
  - major potentially life-threatening bleeding (e.g. multiple trauma)
  - anti-fibrinolytic agents (e.g. tranexamic acid)

Hemophilia B (Factor IX Deficiency)

- i.e. Christmas disease
- X-linked recessive, 1/30,000 males
- clinical and laboratory features identical to hemophilia A (except decreased Factor IX)
- treatment: recombinant Factor IX concentrate, anti-fibrinolytic agents

Factor XI Deficiency

- i.e. Rosenthal syndrome
- autosomal recessive; more common in Ashkenazi Jewish population
- usually mild, often diagnosed in adulthood
- Factor XI level does not correlate with bleeding risk
- treatment: frozen plasma, Factor XI concentrate
Liver Disease

- see Gastroenterology, G28

Pathophysiology
- deficient synthesis of all factors except VIII (also made in endothelium and in acute phase response)
- aberrant synthesis of fibrinogen
- deficient clearance of hemostatic ‘debris’ and fibrinolytic activators
- accelerated destruction due to dysfibrinogenemias: increased fibrinolysis, DIC
- miscellaneous: inhibition of secondary hemostasis by FDPs

Investigations
- peripheral blood film: target cells
- primary hemostasis affected
  - thrombocytopenia 2o to hypersplenism, folate deficiency, alcohol intoxication, DIC, decreased production of thrombopoietin
  - platelet dysfunction (e.g. alcohol abuse)
- secondary hemostasis affected
  - elevated INR (PT), aPTT and TT, low fibrinogen in end-stage liver disease

Treatment
- supportive, treat liver disease, blood products if active bleeding (frozen plasma, platelets, cryoprecipitate)

Vitamin K Deficiency

Etiology
- drugs
  - oral anticoagulants which inhibit Factors II, VII, IX, X, proteins C and S
  - antibiotics eradicating gut flora, altering vitamin K uptake
- poor diet (especially in alcoholics)
- biliary obstruction
- chronic liver disease (decreased stores)
- malabsorption (e.g. celiac disease)
- hemorrhagic disease of newborn, see Pediatrics, P70

Investigations
- INR (PT) is elevated out of proportion to elevation of the aPTT
- decreased Factors II, VII, IX, X (vitamin K-dependent)

Treatment
- hold anticoagulant
- vitamin K 1 mg PO for INR between 4.5 and 10 and no active bleeding (excludes hemorrhagic disease of the newborn)
- if bleeding, give vitamin K 10 mg IV
- if life-threatening bleeding and vitamin K antagonist use, give frozen plasma or prothrombin complex concentrate (PCC)
- PCCs are contraindicated if there is a previous history of HIT
- use FFP if PCC is contraindicated or unavailable
- note: excessive vitamin K will delay therapeutic warfarin anticoagulation once re-started

Disseminated Intravascular Coagulation

- see Obstetrics, OB20

Definition
- uncontrolled release of plasmin and thrombin leading to intravascular coagulation and depletion of platelets, coagulation factors and fibrinogen
- risk of life-threatening hemorrhage

Etiology
- occurs as a complication of many other conditions
- widespread endothelial damage ± extensive inflammatory cytokine release
### Table 28. Etiology of DIC

</tbody>
</table>

### Investigations
- primary hemoestasis: decreased platelets
- secondary hemoestasis: prolonged INR (PT), aPTT, TT, decreased fibrinogen and other factors
- fibrinolysis: increased FDPs or D-dimers, short euglobulin lysis time (i.e. accelerated fibrinolysis)
- extent of fibrin deposition: urine output, urea, RBC fragmentation

### Treatment
- recognize early and treat underlying disorder
- individualized critical care support
- in hemorrhage: replacement of hemostatic elements with platelet transfusion, frozen plasma, cryoprecipitate
  - maintain platelets >50,000/mm³ and hemoglobin >80 g/L
  - 4-5 units of FFP if INR >1.5 or aPTT >38
  - 10 units of cryoprecipitate if fibrinogen <100 mg/dL
  - 1 adult dose of buffy-coat platelets if <10,000 (<20,000 if febrile, <50,000 before invasive procedure)
- in thrombotic phase: UFH or LMWH in critically ill, non-bleeding patients

### Venous Thromboembolism

### Definition
- thrombus formation and subsequent inflammatory response in a superficial or deep vein
- superficial thrombophlebitis, deep vein thrombosis (DVT), and pulmonary embolism (PE)
- thrombi propagate in the direction of blood flow (commonly originating in calf veins)
- more common in lower extremity than upper extremity
- incidence ~1% if age >60 yr
- most important sequelae are pulmonary embolism (~50% chance with proximal DVT) and chronic venous insufficiency
Thromboembolism
- limits development of late complications, e.g., postphlebitic syndrome, chronic venous
- treatment of massive ileofemoral thrombosis with acute lower limb ischemia and/or venous
- reduce the risk of recurrent thrombosis (duration depends on presence of other risk factors)
- prevent acute pulmonary embolism (occurs in up to 50% of untreated patients)
  - age (risk increases with age)
  - surgery (especially orthopedic, thoracic, GI, and GU)
  - trauma (especially fractures of spine, pelvis, femur or tibia, spinal cord injury)
  - neoplasms (especially lung, pancreas, colon, rectum, kidney, and prostate)
  - blood dyscrasias (myeloproliferative neoplasms, especially PV, ET), PNH, hyperviscosity
    (multiple myeloma, polycythemia, leukemia, sickle cell disease)
  - prolonged immobilization (CHF, stroke, MI, leg injury)
  - hormone related (pregnancy, OCP, HRT, SERMs)
  - APS
  - heart failure (risk of DVT greatest with right heart failure and peripheral edema)
- idiopathic (10-20% are later found to have cancer)

Clinical Features of DVT
- absence of physical findings does not rule out disease
- unilateral leg edema, erythema, warmth, and tenderness
- palpable cord (thrombosed vein)
- unilateral leg edema, erythema, warmth, and tenderness
- absence of physical findings does not rule out disease

Differential Diagnosis of DVT
- muscle strain or tear, lymphangitis or lymph obstruction, venous valvular insufficiency,
- venography is the gold standard, but is expensive, invasive, and higher risk
- other non-invasive tests include MRI and impedance plethysmography

Inflammations for DVT
- D-dimer test only useful to rule out DVT if negative with low clinical suspicion of disease and no other acute medical issues
- doppler ultrasound is most useful diagnostic test for DVT
  - sensitivity and specificity for proximal DVT ~ 95%
  - sensitivity for calf DVT ~ 70%
- other non-invasive tests include MRI and impedance plethysmography
- venography is the gold standard, but is expensive, invasive, and higher risk

Post-Thrombotic Syndrome
- development of chronic venous stasis signs and symptoms secondary to a deep venous thrombosis
- symptoms: pain, venous dilatation, edema, pigmentation, skin changes, venous ulcers
- clinical severity can be estimated based on the Villalta score
- large impact on quality of life following a DVT
- treatment: extremity elevation, exercise, continuous compression stockings, intermittent
  pneumatic compression therapy, skin/ulcer care
- for Clinical Features and Treatment of PE, see Respirology. R18

Approach to Treatment of Venous Thromboembolism

Purpose
- prevent further clot extension (3 mo duration is optimal)
- prevent acute pulmonary embolism (occurs in up to 50% of untreated patients)
- reduce the risk of recurrent thrombosis (duration depends on presence of other risk factors)
- treatment of massive ileofemoral thrombosis with acute lower limb ischemia and/or venous gangrene (phlegmasia cerulea dolens)
- limit development of late complications, e.g., postphlebitic syndrome, chronic venous
  insufficiency, and chronic thromboembolic pulmonary HTN

Absolute Contraindications to Treatment

<table>

- Duration of Treatment with Vitamin K Antagonists in Symptomatic Venous Thromboembolism
  - Coccarde SB Syst Rev 2009;300:1367
  - Study: Meta-analysis of 8 RCTs (2,994 patients)
  - comparing different durations of treatment with vitamin K antagonists in patients with symptomatic VTE
  - Results: In patients treated with vitamin K antagonists for a prolonged period, the reduction in risk of recurrent VTE remained consistent regardless of the period of time since the index event (OR 0.18, 95% CI 0.13-0.26). In addition, there was no observed excess of VTE recurrences following cessation of prolonged treatment (i.e., rebound phenomenon) (OR 1.24, 95% CI 0.9-1.38). However, patients who received prolonged treatment had a persistent increase in their risk of major bleeding complications (OR 2.61, 95% CI 1.48-4.61).
  - Conclusion: Prolonged treatment with vitamin K antagonists leads to a consistent reduction in the risk of recurrent VTE for as long as therapy is continued. Therapy should be discontinued when the risk of harm from major bleeding (which remains constant over time) is of greater concern than the absolute risk of recurrent VTE (which declines over time). No specific recommendation was made regarding optimal duration of treatment.
Initial Treatment

- low molecular weight heparin (LMWH)
  - administered SC, at least as effective as UFH with a lower bleeding risk
  - advantages: predictable dose response and fixed dosing schedule; lab monitoring not required; <1% HIT; safe and effective outpatient therapy
  - disadvantages: only partially reversible by protamine, long-term use associated with osteoporosis
  - renally cleared – must adjust dose in patients with renal dysfunction
- unfractionated heparin (UFH)
  - in patient with average risk of bleed; use hospital-based nomograms that use bleeding risk and patient weight to determine appropriate dose
  - advantages: rapidly reversible by protamine
  - disadvantages: must monitor aPTT with adjustment of dose to reach therapeutic level (~2x normal value); monitor platelet counts for development of HIT
- alternatives to LMWH and UFH
  - heparinoids (patients with HIT), direct thrombin inhibitors (hirudin, lepirudin, argatroban, dabigatran), Factor Xa inhibitors (fondaparinux, rivaroxaban)
  - thrombolytic drugs (e.g. streptokinase, tPA) reserved for acute limb/life-threatening thrombosis, and low bleeding risk

Long-Term Treatment

- warfarin
  - standard treatment; should be initiated with heparin overlap: dual therapy for at least 5 d, due to initial prothrombotic state, half life of vitamin K factors and risk of warfarin-induced skin necrosis
  - discontinue heparin after INR >2.0 for two consecutive days
  - warfarin should be dosed to maintain INR at 2-3 except in select cases
  - monitor INR twice weekly for 1-2 wk, then weekly until INR stable, then every 2-4 wk
  - LMWH more effective than warfarin at preventing recurrence of venous thrombosis in cancer patients (see sidebar, H34)
  - duration of anticoagulant treatment (with warfarin unless otherwise noted)
    - first episode DVT with transient risk factor: 3 mo
    - first episode DVT with ongoing risk factor (e.g. cancer, antiphospholipid antibody) or >1 risk factor: consider indefinite therapy
    - first episode DVT with no identifiable risk factor (idiopathic) or single inherited risk factor (e.g. Factor V Leiden): 6-12 mo or indefinite therapy (controversial)
    - recurrent DVT (2 or more episodes): indefinite therapy
  - IVC filters
    - temporary filter indicated only if distal acute DVT (<4 wk) with significant contraindications to anticoagulant therapy (i.e. active bleeding)
    - must remove once safe to do so as filter is pro-thrombotic in the longterm (anticoagulation if left in)
  - special considerations
    - pregnancy: treat with LMWH during pregnancy, then warfarin for 4-6 wk post-partum (minimum total anticoagulation time of 3-6 mo)
    - surgery: avoid elective surgery in the first month after a venous or arterial thromboembolic event
      - pre-operatively: IV heparin may be used up to 6 h pre-operatively
      - perioperatively: surgery safe when INR <1.5; warfarin should be discontinued for at least 4 wk pre-operatively to allow INR to fall
      - post-operatively: IV heparin or LMWH can be used for anticoagulation (start 12 h after major surgery until therapeutic INR reached after restarting warfarin)
      - for patients at high risk for thromboembolism (VTE <12 wk, recurrent VTE, lupus anticoagulant, atrial fibrillation with prior stroke, mechanical heart valve), IV heparin or LMWH (bridging) should be given before and after the procedure while the INR is below 2.0

Prophylaxis

- see sidebar
- consider for those with a moderate to high risk of thrombosis without contraindications
- non-pharmacological measures include: early ambulation, elastic compression stockings (TEDs), intermittent pneumatic compression (IPC)
- UFH 5,000 IU SC bid for moderate risk
- UFH 5,000 IU SC tid or LMWH as per hospital protocol (i.e. enoxaparin 40 mg SC daily) or UFH 5,000 IU SC tid for high risk

Contraindications and Adverse Reactions of Anticoagulant Therapy

- absolute: active bleeding, severe bleeding diathesis, or platelets <20 x 10^9/L (<20,000/mm^3), intracranial bleeding, neuro or ocular surgery within <10 d
- relative: mild-moderate neurologic diathesis or thrombocytopenia, brain metastases, recent major trauma, major abdominal surgery within page 2 d, GI/GU bleed within 14 d, endocarditis, severe HTN (sBP >200 or dBP >120), recent stroke

Treatment of Pulmonary Embolism

- see Respirology, R20

Common Medications that Interact with Warfarin

- Acetaminophen (interaction with vitamin K metabolism)
- Alemtuzumab
- NSAIDs (GI injury)
- Fluconazole
- Metronidazole
- Sulfamethoxazole
- Tamoxifen

Initiation of Warfarin Therapy Requires Overlap with Heparin Therapy for 4-5 d

- 10 mg loading dose of warfarin causes a precipitous decline in protein C levels in first 36 h resulting in a transient hypercoagulable state
- Warfarin decreases Factor VII levels in first 48 h INR is prolonged (most sensitive to Factor VII levels), however full antithrombotic effect is not achieved until Factor IX, X, and II are sufficiently reduced (occurs after ~4 d)

Low Risk Surgical Patients

- <40 yr, no risk factors for VTE, general anesthetic (GA) <30 min, minor elective, abdominal, or thoracic surgery

Moderate Risk Surgical Patients

- >40 yr, >1 risk factor for VTE, GA >30 min

High Risk Surgical Patients

- > yr, surgery for malignancy or lower extremity orthopedic surgery lasting >30 min, inhibitor deficiency, or other risk factor

High Risk Medical Patients

- Heart failure, severe respiratory disease, ischemic stroke and lower limb paralysis, confined to bed and have >1 additional risk factor (e.g. active cancer, previous VTE, sepsis, acute neurologic disease, BD)
Hypercoagulable Disorders

Hypercoagulability Workup – Venous Thrombosis

- workup for malignancy or hypercoagulable state indicated for idiopathic VTE in presence of the following: age <50, recurrent VTE, family history of VTE and age <50, unusual site of DVT (portal, hepatic, mesenteric vascular beds), heparin-resistant disease (AT deficiency), warfarin-induced skin necrosis or neonatal purpura fulminans (proteins C or S deficiency); consider for women with VTE within 12 mo of exposure to OCP
- workup
  - initial
    - CBC, blood smear, coagulation studies, liver/renal function, urinalysis, fasting homocysteine
    - malignancy workup (see sidebar)
    - antiphospholipid antibodies (APLA): anticardiolipin antibodies (ACA) and lupus anticoagulant (LA)
    - activated protein C resistance (APCR)
    - DNA/Molecular: FVL (Factor V Leiden), PT (prothrombin G20210A), JAK-2
    - Flow Cytometry: PNH
    - post initial insult (>72 h) (as protein levels depleted/consumed by clot)
      - antithrombin (not on heparin)
      - Factor VIII (increased levels predict recurrence)
      - post-treatment
        - proteins C, S (not on warfarin)
- Note: most of these tests do not change management, and a negative test does not rule out a hypercoagulable state. Thus more focus is on the reversible/treatable causes (APLA, cancer, etc.)

CAUSES OF HYPERCOAGULABILITY LEADING TO VENOUS THROMBOEMBOLISM

Activated Protein C Resistance (Factor V Leiden)
- most common cause of hereditary thrombophilia
- 5% of general population are heterozygotes
- point mutation in the Factor V gene (R506Q) results in resistance to inactivation of Factor Va by activated protein C

Prothrombin (PT) G20210A
- G to A transposition at nucleotide position 20210 of the prothrombin gene promoter region results in increased levels of prothrombin, thus increased thrombin generation

Protein C and Protein S Deficiency
- protein C inactivates Factor Va and VIIIa using protein S as a cofactor
- protein C deficiency
  - homozygous: neonatal purpura fulminans
  - heterozygous:
    - type I: decreased protein C levels
    - type II: decreased protein C activity
    - acquired: liver disease, sepsis, DIC, warfarin
    - 1/3 of patients with warfarin necrosis have underlying protein C deficiency
- protein S deficiency
  - type I: decreased free and total protein S levels
  - type II: decreased protein S activity
  - type III: decreased free protein S levels
  - acquired: liver disease, DIC, pregnancy, nephrotic syndrome, inflammatory conditions, warfarin

Antithrombin Deficiency
- antithrombin slowly inactivates thrombin in the absence of heparin, rapidly inactivates thrombin in the presence of heparin
- autosomal dominant inheritance or urinary losses in nephrotic syndrome
  - type I: decreased AT levels
  - type II: decreased AT activity
  - diagnosis must be made outside window of acute thrombosis and anticoagulation treatment (acute thrombosis, heparin, systemic disease all decrease antithrombin levels)
  - deficiency may result in resistance to unfractionated heparin (LMWH must be used)

Elevated Factor VIII Levels
- an independent marker of increased thrombotic risk
- genetic basis for increased levels poorly understood

Disorders of Fibrinolysis
- include congenital plasminogen deficiency, tissue plasminogen activator deficiency

Antiphospholipid Antibody Syndrome (APS)
- definition: ≥1 clinical and ≥1 laboratory criteria
  - clinical: thrombosis, spontaneous abortions, fetal loss, premature birth before 34 wk
  - laboratory: antiphospholipid or lupus anticoagulant antibodies
  - mechanism: not well understood, antibodies interact with platelet membrane phospholipid causing increased adhesion and aggregation; can also interfere with action of proteins C and S
- see Rheumatology, RH12

Common Causes of Hypercoagulability

- CALM APES
  - Protein C deficiency
  - Antiphospholipid Ab
  - Factor V Leiden
  - Malignancy
  - Antithrombin deficiency
  - Prothrombin G20210A
  - Increased Factor VIII (Eight)
  - Protein S deficiency

Although lupus anti-coagulant prolongs PTT, its main clinical feature is thrombosis

Protein C, protein S, and ATIII are decreased during acute thrombosis – therefore to test for deficiency, must be tested outside of this time period

Causes of Both Venous and Arterial Thrombosis include:

- Antiphospholipid antibodies
- Myeloproliferative neoplasms
- Heparin induced thrombocytopenia
- Distal venous clot with patent foramen ovale

Malignancy is a common cause of acquired hypercoagulability

Workup may include (controversial):
- Complete history and physical
- Routine blood work
- Urinalysis
- CXR and abdominal ultrasound
- Age appropriate screening: mammogram, Pap, PSA, colonoscopy
- Close follow-up

Disorders of Fibrinolysis
- include congenital plasminogen deficiency, tissue plasminogen activator deficiency

Antiphospholipid Antibody Syndrome (APS)
- definition: ≥1 clinical and ≥1 laboratory criteria
  - clinical: thrombosis, spontaneous abortions, fetal loss, premature birth before 34 wk
  - laboratory: antiphospholipid or lupus anticoagulant antibodies
  - mechanism: not well understood, antibodies interact with platelet membrane phospholipid causing increased adhesion and aggregation; can also interfere with action of proteins C and S
- see Rheumatology, RH12
**Hematologic Malignancies and Related Disorders**

**Acute Myeloid Leukemia**

**Definition**
- rapidly progressive malignancy characterized by failure of myeloid cells to differentiate beyond blast stage

**Epidemiology**
- incidence increases with age; median age of onset is 65 yr old
- accounts for 10-15% of childhood leukemias

**Risk Factors**
- myelodysplastic syndromes (MDS), benzene, radiation, alkylating agents as treatment for previous malignancy

**Pathophysiology**
- etiology subdivided into
  - primary: *de novo*
  - secondary: hematologic malignancies (e.g. myeloproliferative disorders and MDS) or previous chemotherapeutic agents (e.g. alkylating agents)
- uncontrolled growth of blasts in marrow leads to
  - suppression of normal hematopoietic cells
  - appearance of blasts in peripheral blood
  - accumulation of blasts in other sites (e.g. skin, gums)
  - metabolic consequences; tumor lysis syndrome

**Clinical Features**
- anemia, thrombocytopenia (associated with DIC in PML), neutropenia (even with normal WBC), leads to infections, fever
- thrombocytopenia (associated with DIC in promyelocytic leukemia)
- accumulation of blast cells in marrow
  - skeletal pain, bony tenderness (especially sternum)
- organ infiltration
  - gingival hypertrophy (particularly myelomonocytic leukemia) – may present to dentist first
  - hepatosplenomegaly (in AML)
  - lymphadenopathy (not marked)
- skin: leukemia cutis
- gonads (in ALL)
- eyes: Roth spots, cotton wool spots, vision changes (uncommon)
- leukostasis/hyperleukosis syndrome (medical emergency)
- large numbers of blasts interfere with circulation and lead to hypoxia and hemorrhage – can cause diffuse pulmonary infiltrates, CNS bleeding, respiratory distress, altered mental status, priapism

---

**Typical Age of Presentation of Leukemias**
- ALL: Children and older adults
- CML: 40-60 yr
- AML, CLL: >60 yr

**Leukemia:** malignancies arise in bone marrow and may spread elsewhere (including blood and lymphoid tissue)

**Lymphoma:** malignancies arise in lymph nodes and lymphoid tissues and may spread elsewhere (including blood and bone marrow)

**BUT** the location where the malignant cells are found does not solely define the type of hematologic malignancy – classified based on the characteristics of the cell (histology, histochemistry, immunophenotyping, cytogenetics, molecular changes)

**Acute Leukemia**
**Definition (WHO):** presence of 20% blast cells or greater in bone marrow at presentation
**Classification:** divided into myeloid (AML) and lymphoid (ALL) depending on whether blasts are myeloblasts or lymphoblasts, respectively

**Auer rods are pathognomonic for AML**

**2008 WHO Classification of AML and Related Neoplasms**
- AML with recurrent genetic abnormalities
- AML with myelodysplasia-related changes
- Therapy-related myeloid neoplasms
- Myeloid sarcoma
- Myeloid proliferations related to Down syndrome
- Blastic plasmacytoid dendritic cell neoplasm
- AML, not otherwise specified (equivalent FAB classification)
  - Undifferentiated (M1)
  - Myeloblastic (M2)
  - Promyelocytic (M3)
  - Myelomonocytic (M4)
  - Monocytic (M5)
  - Erythroleukemic (M6)
  - Megakaryocytic (M7)
- Acute basophilic leukemia
- Acute panmyelosis with myelofibrosis
• metabolic effects; aggravated by treatment (rare)
  ▪ increased uric acid → nephropathy, gout
  ▪ release of phosphate → decreased Ca\textsuperscript{2+}, decreased Mg\textsuperscript{2+}
  ▪ release of procoagulants → DIC (higher risk in acute promyelocytic leukemia)
• decreased or normal K\textsuperscript{+} before treatment, increased K\textsuperscript{+} after treatment (from lysed cells)

**Investigations**
• blood work
  ▪ CBC: anemia, thrombocytopenia, variable WBC
  ▪ INR, aPTT, fibrin degradation products (FDP), fibrinogen (in case of DIC)
  ▪ increased LDH, increased uric acid, increased PO\textsubscript{4}\textsuperscript{3-} (released by leukemic blasts), decreased Ca\textsuperscript{2+}
  ▪ baseline renal and liver function tests
• peripheral blood film – circulating blasts with Auer rods (azurophilic granules) are pathognomonic for AML
• bone marrow aspirate
  ▪ blast count: AML >20% (normal is <5%)
  ▪ morphologic, cytochemical, and/or immunotypic features are used to establish lineage and maturation (see sidebar for WHO classification of AML, H37)
• CXR to rule out pneumonia, ECG, MUGA scan prior to chemotherapy (cardiotoxic)

**Treatment**
• mainstay of treatment is chemotherapy (rapidly fatal without treatment)
  ▪ all AML subtypes treated similarly except promyelocytic variant with t(15:17) translocation
    ▪ all-trans-retinoic acid (ATRA) added to induce differentiation; arsenic trioxide + ATRA combination therapy for APL is non-inferior to traditional chemotherapy
• treatment strategy
  1. **Induction:** chemotherapy to induce complete remission of AML (see sidebar)
     ▪ several possible regimens (e.g. cytarabine with anthracycline [daunorubicin])
     ▪ patients with poor response to initial induction therapy – worse prognosis
     ▪ must ensure reversal of DIC, platelet transfusions if <10
  2. **Consolidation:** to prevent recurrence
     ▪ intensive consolidation chemotherapy
     ▪ stem cell transplantation – autologous or allogeneic (younger patients with better performance status)
     ▪ consider acceleration with hematopoietic growth factors (e.g. G-CSF) if severe infection develops
• supportive care
  ▪ screening for infection via regular C&S of urine, stool, sputum, oropharynx, catheter sites, perianal area
  ▪ fever: C&S of all orifices, CXR, start antibiotics
  ▪ platelet and RBC transfusions (irradiated to prevent transfusion-related GVHD) ± EPO
  ▪ prevention and treatment of metabolic abnormalities
    ▪ allopurinol, rasburicase for prevention of hyperuricemia

**Prognosis**
• achievement of first remission
  ▪ 70-80% if ≤60 yr old, 50% if >60 yr old
  ▪ median survival 12-24 mo
  ▪ 5 yr survival 40%
• prognosis related to cytogenetics (favorable, intermediate, or adverse)

---

**Myelodysplastic Syndromes**

**Definition**
• heterogeneous group of malignant stem cell disorders characterized by dysplastic and ineffective blood cell production resulting in peripheral cytopenias
• syndromes defined according to World Health Organization (WHO) classifications (see sidebar)

**Pathophysiology**
• disordered maturation: ineffective hematopoiesis despite presence of adequate numbers of progenitor cells in bone marrow (usually hypercellular)
• intramedullary apoptosis: programmed cell death within bone marrow
  ▪ both processes lead to reduced mature cells in periphery
  ▪ <30% develop AML

**Risk Factors**
• elderly, post-chemotherapy, benzene or radiation exposure
• occurs in 60/100,000 in patients >60 yr old
Clinical Features
- insidious onset: associated with those of pancytopenia
- infections and bleeding out of proportion with peripheral blood counts

Investigations
- diagnosed by
  - anemia ± thrombocytopenia ± neutropenia
  - CBC and peripheral blood film
  - RBC: usually macrocytic with oval shaped red cells (macro-ovalocytes), decreased reticulocyte count
  - WBC: decreased granulocytes and abnormal morphology (e.g. bilobed or unsegmented nuclei = Pelger abnormality)
  - platelets: thrombocytopenia, abnormalities of size and cytoplasm (e.g. giant hypogranular platelets)
- bone marrow aspirate and biopsy with cytogenetic analysis required for definitive diagnosis
  - bone marrow: dysplastic and often normocellular/hypercellular
  - cytogenetics: partial or total loss of chromosomes 5, 7, Y, or trisomy 8

Prognosis
- Revised International Prognostic Scoring System (IPSS-R) uses 5 factors to estimate mean survival
  - cytology, % bone marrow blasts, hemoglobin, platelets, absolute neutrophil count
  - based on the calculated score, a patient’s MDS prognostic risk is “Very Low”, “Low”, “Intermediate”, “High”, or “Very High” with a mean survival of 8.7, 5.3, 3.0, 1.6, and 0.8 yr, respectively

Treatment
- low risk of transformation to acute leukemia (IPSS-R Very Low or Low)
  - erythropoietin stimulating agents weekly is first line in reducing transfusion requirements
  - 5q(-) cytogenetic: lenalidomide PO
  - supportive care: RBC and platelet transfusion (consider iron chelation if frequent RBC transfusions)
- high risk of transformation to acute leukemia (IPSS-R Intermediate, High or Very High)
  - supportive care
  - stem cell transplantation if age <65 yr
  - epigenetic therapy: DNA methyltransferase inhibitors (e.g. 5-azacytidine), histone deacetylase inhibitors

Myeloproliferative Neoplasms

Definition
- clonal myeloid stem cell abnormalities leading to overproduction of one or more cell lines (leading to abnormalities in erythrocytes, platelets, and other cells of myeloid lineage)

Epidemiology
- mainly middle-aged and older patients (peak 60-80 yr)

Prognosis
- may develop marrow fibrosis with time
- all disorders may progress to AML

CML = chronic myeloid leukemia; ET = essential thrombocythemia; IMF = idiopathic myelofibrosis; PV = polycythemia vera
Chronic Myeloid Leukemia

Definition
• myeloproliferative disorder characterized by increased proliferation of the granulocytic cell line without the loss of their capacity to differentiate

Epidemiology
• occurs in any age group (mostly middle age to elderly) with a median age of 65 yr

Pathophysiology
• Philadelphia chromosome (Ph)
  • translocation between chromosomes 9 and 22
  • the c-abl proto-oncogene is translocated from chromosome 9 to “breakpoint cluster region” (bcr) of chromosome 22 to produce bcr-abl fusion gene, an active tyrosine kinase

Clinical Features
• 3 clinical phases
  • **chronic phase**: 85% diagnosed here
    • few blasts (<10%) in peripheral film
    • ± slightly elevated eosinophils and basophils
  • **accelerated phase**: impaired neutrophil differentiation
    • circulating blasts (10-19%) with increasing peripheral basophils (pruritus)
  • **blast crisis**: more aggressive course, blasts fail to differentiate
    • blasts (>20%) in peripheral blood or bone marrow; reflective of acute leukemia (1/3 ALL, 2/3 AML)
  • **clinical presentation**
    • 20-50% of patients are asymptomatic when diagnosed (incidental lab finding)
    • nonspecific symptoms
      • fatigue, weight loss, malaise, excessive sweating, fever
    • secondary to splenic involvement
      • early satiety, LUQ pain/fullness, shoulder tip pain (referred)
      • splenomegaly (most common physical finding)
    • anemia
    • bleeding: secondary to platelet dysfunction
    • pruritus, PUD: secondary to increased blood histamine
    • leukostasis, priapism, encephalopathy (rare): secondary to very elevated WBC (rare)

Investigations
• high increase in WBC, decreased/normal RBC, increased/decreased platelets, increased basophils
• WBC differential shows a bimodal distribution, with predominance of myelocytes and neutrophils
• peripheral blood film
  • leukoerythroblastic picture (immature red cells and granulocytes present, e.g. myelocytes and normoblasts)
• presence of different mid-stage progenitor cells differentiates it from AML
• bone marrow
  • myeloid hyperplasia with left shift, increased megakaryocytes, mild fibrosis
  • molecular and cytogenetic studies of bone marrow or peripheral blood for Philadelphia chromosome
• abdominal imaging for spleen size

Treatment
• symptomatic
  • allopurinol and antihistamines
• chronic phase
  • imatinib mesylate inhibits proliferation and induces apoptosis by inhibiting tyrosine kinase activity in cells positive for bcr-abl
    • if loss of response or intolerance (~25%), trial of 2nd (dasatinib, nilotinib) or 3rd generation inhibitors
    • dasatinib may be considered for first line management (see sidebar)
  • interferon-α: may improve response to tyrosine kinase inhibitors
  • hydroxyurea in palliative setting
  • bone marrow transplantation if progression to accelerated or blast phases: CML (curative)
• accelerated phase or blast phase
  • refer for clinical trial or 2nd/3rd generation (ponatinib only for T315I-mutated CML) TKI and prepare for allogeneic stem cell transplant patients, in blast phase typically get standard AML induction
  • stem cell transplantation may be curative: to be considered in young patients who do not meet therapeutic milestones

Detection of the bcr-abl fusion gene is a diagnostic test for CML (present in over 90% of patients)

Early Response with Dasatinib or Imatinib in Chronic Myeloid Leukemia
Blood 2014;123:494-500
Study: The DASatinib vs. Imatinib Study in Treatment-Naïve CML patients (DASISION) trial is a randomized phase 3 trial comparing treatment with dasatinib (n=259) or imatinib (n=260) once daily in patients with newly diagnosed CML in chronic phase.
Results: Dasatinib was associated with superior efficacy during the first year of treatment, including significantly higher complete cytogenetic responses (63% vs. 72%) and major molecular responses (64% vs. 28%) compared to imatinib, respectively. Dasatinib was associated with faster and deeper responses at 3, 6, and 12 mo.
Clinical Features
• symptoms are secondary to high red cell mass and hyperviscosity (see Erythrocytosis, H6)
  • bleeding complications: epistaxis, gingival bleeding, echymoses, and GI bleeding
  • due to platelet abnormalities
  • thrombotic complications: DVT, PE, thrombophlebitis, increased incidence of stroke, MI
  • due to increased blood viscosity, increased platelet number and/or activity
  • erythromelalgia (burning pain in hands and feet and erythema of the skin)
  • associated with platelets >400,000/mm³
  • pathognomonic microvascular thrombotic complication in PV and ET
• pruritus, especially after warm bath or shower (40%)
• due to cutaneous mast cell degranulation and histamine release
• epigastric distress, PUD
• due to increased histamine from tissue basophils, alterations in gastric mucosal blood flow
• due to increased blood viscosity
• gout (hyperuricemia)
• due to increased cell turnover
• characteristic physical findings
  • plethora (ruddy complexion) of face (70%), palms
  • splenomegaly (70%), hepatomegaly (40%)

Investigations
• see Erythrocytosis, H6
• must rule out secondary polycythemia
• diagnosis (WHO 2008) requires either both major criteria plus one minor criteria OR the first major criterion plus 2 minor criteria
  • Major Criteria
    1. hemoglobin >18.5 g/dL in men, 16.5 g/dL in women or other evidence of increased red cell volume
    2. presence of JAK2 V617F or other functionally similar mutation such as JAK2 exon 12 mutation
  • Minor Criteria
    1. bone marrow biopsy showing hypercellularity for age with trilineage growth (panmyelosis) with prominent erythroid, granulocytic, and megakaryocytic proliferation
    2. serum erythropoietin level below the reference range for normal
    3. endogenous erythroid colony formation in vitro

Treatment
• phlebotomy to keep hematocrit <45%
• hydroxyurea (prior thrombosis or symptoms, severe coronary artery disease, refractory to phlebotomy)
• low-dose Aspirin® (for antithrombotic prophylaxis, will also treat erythromelalgia)
• allopurinol: as needed
• antihistamines: as needed

Prognosis
• 10-20 yr survival with treatment
• complicated by thrombosis, hemorrhage, leukemia transformation (AML)
**Idiopathic Myelofibrosis**

**Definition**
- excessive bone marrow fibrosis leading to marrow failure
- characterized by anemia, extramedullary hematopoiesis, leukoerythroblastosis, teardrop red cells in peripheral blood and hepatosplenomegaly

**Epidemiology**
- rare, median age at presentation is 65 yr

**Pathophysiology**
- abnormal myeloid precursor postulated to produce dysplastic megakaryocytes that secrete fibroblast growth factors
  - stimulates fibroblasts and stroma to deposit collagen in marrow
- increasing fibrosis causes early release of hematopoietic precursors leading to:
  - leukoerythroblastic blood film (primitive RBCs and WBCs present in blood)
  - migration of precursors to other sites: extramedullary hematopoiesis (leading to hepatosplenomegaly)
  - mutations in JAK2, c-mpl, and calreticulin define the clone

**Clinical Features**
- anemia (severe fatigue is most common presenting complaint, pallor on exam in >60%)
- weight loss, fever, night sweats → secondary to hypermetabolic state
- splenomegaly (90%) → secondary to extramedullary hematopoiesis; may cause early satiety
- hepatomegaly (70%) → may get portal HTN
- bone and joint pain → secondary to osteosclerosis, gout
- signs of extramedullary hematopoiesis (depends on organ involved)

**Investigations**
- CBC: anemia, variable platelets, variable WBC
- biochemistry: increased ALP (liver involvement, bone disease), increased LDH (2° to ineffective hematopoiesis), increased uric acid (increased cell turnover), increased B12 (2° to increased neutrophil mass)
- blood film: leukoerythroblastosis with teardrop RBCs, nucleated RBCs, variable polychromasia, large platelets, and megakaryocyte fragments
- JAK2 PCR
- bone marrow aspirate: “dry tap” in as many as 50% of patients (no blood cells aspirated)
- bone marrow biopsy (essential for diagnosis): fibrosis, atypical megakaryocytic hyperplasia, thickening and distortion of the bony trabeculae (osteosclerosis)

**Treatment**
- allogeneic stem cell transplant is potentially curative
- JAK2 inhibitors
- symptomatic treatment
  - transfusion for anemia
  - erythropoietin: 30-50% of patients respond
  - androgens (e.g., danazol has shown transient response with response rates of <30%)
  - hydroxyurea for splenomegaly, thrombocytosis, leukocytosis, systemic symptoms
  - α-interferon (as second line therapy)
  - splenectomy (as third line therapy; associated with high mortality and morbidity)
  - radiation therapy for symptomatic extramedullary hematopoiesis, symptomatic splenomegaly
  - thalidomide, and etanercept may improve quality of life and spleen size, but not survival

**Prognosis**
- International Prognostic Scoring System (IPSS) for IMF uses 5 factors to determine mean survival
  - presence of constitutional symptoms; age >65; hemoglobin <10.0 g/dL; leukocyte count >25,000/mm3; circulating blast cells ≥1%
  - based on the calculated score, a patient's IMF is categorized as “low,” “intermediate 1,” “intermediate 2,” or “high” with a mean survival of 135, 95, 48, and 27 mo respectively
  - risk of transformation to AML (8-10%)

**Essential Thrombocytemia**

**Definition**
- overproduction of platelets in the absence of recognizable stimulus
- must rule out secondary thrombocytemia
Clinical Features

- often asymptomatic
- vasomotor symptoms (40%)
  - headache (common), dizziness, syncope
  - erythromelalgia (burning pain of hands and feet, dusky color, usually worse with heat, caused by platelet activation → microvascular thrombosis)
- thrombosis (arterial and venous)
- bleeding (often GI, associated with platelets >1,000,000/mm^3)
- constitutional symptoms, splenomegaly
- pregnancy complications; increased risk of spontaneous abortion
- risk of transformation to AML (0.6-5%), myelofibrosis

Treatment

- low dose ASA if previous history of thrombotic event, ≥1 cardiovascular risk factors, older, or symptomatic
- cytoreductive therapy if thrombosis or thrombotic symptoms: hydroxyurea (HU) (1st line therapy), anagrelide, interferon-α, or 32P (age >80 or lifespan <10 yr)
- splenectomy not recommended (increased risk of bleeding episodes, thrombosis)

Lymphoid Malignancies

Acute Lymphoblastic Leukemia

Definition

- malignant disease of the bone marrow in which early lymphoid precursors proliferate and replace the normal hematopoietic cells of the marrow
- WHO subdivides ALL into two types depending on cell of origin
  1. B-cell: precursor B lymphoblastic leukemia
  2. T-cell: precursor T lymphoblastic leukemia
- The French-American-British (FAB) classification (L1, L2, L3) is no longer encouraged, as WHO subdivides ALL into two types depending on cell of origin

Clinical Features

- see Acute Myeloid Leukemia, H37 for full list of symptoms
- distinguish ALL from AML based on Table 32
- clinical symptoms usually secondary to:
  - bone marrow failure: anemia, neutropenia (50% present with fever; also infections of oropharynx, lungs, perianal region), thrombocytopenia
  - organ infiltration: tender bones, lymphadenopathy, hepatosplenomegaly, meningeval signs (headache, N/V, visual symptoms; especially in ALL relapse)

Investigations

- CBC: increased leukocytes >10 x 10^9/L (occurs in 50% of patients); neutropenia, anemia, or thrombocytopenia
- may have increased uric acid, K^+, PO_4^3-, Ca^{2+}, LDH
- PT, aPTT, fibrinogen, D-dimers for DIC
- leukemic lymphoblasts lack specific morphological (no granules) or cytochemical features, therefore diagnosis depends on immunophenotyping
- cytogenetics: Philadelphia (Ph) chromosome in ~25% of adult ALL cases
• CXR: patients with ALL may have a mediastinal mass
• LP prior to systemic chemotherapy to assess for CNS involvement (ensure adequate platelet count and PT/PTT)

Treatment
• eliminate abnormal cloned cells
  1. Induction: to induce complete remission (undetectable leukemic blasts, restore normal hematopoiesis)
  2. Consolidation and/or intensification chemotherapy
     • consolidation: continuing same chemotherapy to eliminate subclinical leukemic cells
     • intensification: high doses of different (non-cross-reactive) chemotherapy drugs to eliminate cells with resistance to primary treatment
  3. Maintenance chemotherapy: low dose intermittent chemotherapy over prolonged period (2-3 yr) to prevent relapse
  4. Prophylaxis: Methotrexate (intrathecal or systemic) or CNS radiation therapy
     • hematopoietic stem cell transplantation: potentially curative (due to pre-implant myeloablative chemoradiation and post-implant graft-versus-leukemia effect) but relapse rates and non-relapse mortality high

Prognosis
• depends on response to initial induction or if remission is achieved following relapse
• good prognostic factors: young, WBC  $< 30 \times 10^9/L$, T-cell phenotype, absence of Ph chromosome, early attainment of complete remission
• achievement of first remission: 60-90%
• childhood ALL: 80% long-term remission (>5 yr)
  • higher cure rates in children because of better chemotherapy tolerance, lower prevalence of \( bcr-abl \) fusion gene (associated with chemotherapeutic resistance)
• adult ALL: 30-40% 5 yr survival

Lymphomas

Definition
• collection of lymphoid malignancies in which malignant lymphocytes accumulate at lymph nodes and lymphoid tissues
  • leading to lymphadenopathy, extranodal disease, and constitutional symptoms

Table 33. Ann Arbor System for Staging Lymphomas

Hodgkin Lymphoma

Definition
- malignant proliferation of lymphoid cells with Reed-Sternberg cells (thought to arise from germinal center B-cells)

Epidemiology
- bimodal distribution with peaks at 20 yr and >50 yr
- association with Epstein-Barr virus in up to 50% of cases, causal role not determined

Clinical Features
- asymptomatic lymphadenopathy (70%)
  - non-tender, rubbery consistency
  - cervical/supraclavicular (60-80%), axillary (10-20%), inguinal (6-12%)
  - splenomegaly (50%) ± hepatomegaly
- mediastinal mass
  - found on routine CXR, may be symptomatic (cough)
  - rarely may present with SVC syndrome, pleural effusion
- systemic symptoms
  - B symptoms (especially in widespread disease; fever in 30%), pruritus
  - non-specific/paraneoplastic
  - alcohol-induced pain in nodes, nephrotic syndrome
  - starts at a single site in lymphatic system (node), spreads first to adjacent nodes
  - disease progresses in contiguity with lymphatic system

Investigations
- CBC
  - anemia (chronic disease, rarely hemolytic), eosinophilia, leukocytosis, platelets normal or increased early, decreased in advanced disease
- biochemistry
  - HIV serology
  - LFTs (liver involvement)
  - RFTs (prior to initiating chemotherapy)
  - ALP, Ca²⁺ (bone involvement)
  - ESR, LDH (monitor disease progression)
- imaging
  - CXR, CT chest (lymph nodes, mediastinal mass), CT abdomen/pelvis (liver or spleen involvement), gallium scan (assess treatment response), PET scans
  - cardiac function assessment (MUGA scan or echocardiography): for patients at high risk of pre-treatment cardiac disease (age >60, history of HTN, CHF, PUD, CAD, MI, ČVA), treatment can be cardiotoxic
  - PFTs: if history of lung disease (COPD, smoking, previous radiation to lung)
  - excisional lymph node biopsy confirms diagnosis
  - bone marrow biopsy to assess marrow infiltration (only necessary if B-symptoms, stage III or IV, bulky disease or cytopenia)

Treatment
- stage I-II: chemotherapy (ABVD) followed by involved field radiotherapy (XRT)
- stage III-IV: chemotherapy (ABVD) with XRT for bulky disease
- relapse, resistant to therapy: high dose chemotherapy, bone marrow transplant
- new imaging modalities increasingly used including PET scans used to follow response to treatment

Complications of Treatment
- cardiac disease: secondary to XRT, adriamycin is also cardiotoxic
- pulmonary disease: secondary to bleomycin (interstitial pneumonitis)
- infertility: recommend sperm banking
- secondary malignancy in irradiated field
  - <2% risk of MDS, AML (secondary to treatment, usually within 8 yr)
  - solid tumors of lung, breast; >8 yr after treatment
- non-Hodgkin lymphoma
- hypothyroidism: post XRT
**Prognosis**

- **Hasenclever adverse prognostic factors**
  1. serum albumin <40 g/L (4 g/dL)
  2. hemoglobin <105 g/L (10.5 g/dL)
  3. male
  4. stage IV disease
  5. age ≥45 yr
  6. leukocytosis (WBC >1,500/mm³)
  7. lymphocytopenia (lymphocytes <60/mm³ or <8% of WBC count or both)

- **prognostic score**
  - each additional adverse prognostic factor decreases freedom from progression at 5 yr (FFP)

**Non-Hodgkin Lymphoma**

**Definition**

- malignant proliferation of lymphoid cells of progenitor or mature B- or T-cells

**Classification**

- multiple classification systems exist at present and may be used at different centers
- can originate from both B- (85%) and T- or NK- (15%) cells
  - B-cell NHL: e.g. diffuse large B-cell lymphoma, follicular lymphoma, Burkitt’s lymphoma, mantle cell lymphoma
  - T-cell NHL: e.g. mycosis fungoides, anaplastic large cell lymphoma
- WHO/REAL classification system: 3 categories of NHLs based on natural history
  - **indolent** (35-40% of NHL): e.g. follicular lymphoma, small lymphocytic lymphoma/CLL
  - **aggressive** (~50% of NHL): e.g. diffuse large B-cell lymphoma
  - **highly aggressive** (~5% of NHL): e.g. Burkitt’s lymphoma
- Note: mantle cell lymphoma (7% of NHL) may have features of aggressive or indolent lymphoma

**Clinical Features**

- painless superficial lymphadenopathy, usually >1 lymph node region
- usually presents as widespread disease (exception is aggressive lymphoma)
- constitutional symptoms not as common as in Hodgkin lymphoma
- cytopenia: anemia ± neutropenia ± thrombocytopenia can occur when bone marrow is involved
- abdominal signs
  - hepatosplenomegaly
  - retroperitoneal and mesenteric involvement (second most common site of involvement)
  - oropharyngeal involvement in 5-10% with sore throat and obstructive apnea
  - extranodal involvement: most commonly GI tract; also testes, bone, kidney
  - CNS involvement in 1% (often with HIV)

**Investigations**

- **CBC**
  - normocytic normochromic anemia
  - autoimmune hemolytic anemia
  - advanced disease: thrombocytopenia, neutropenia, and leukoerythroblastic anemia
- peripheral blood film may show lymphoma cells
- flow cytometry of peripheral blood is valuable for low-grade NHL
- biochemistry
  - increase in uric acid
  - abnormal LFTs in liver metastases
  - increased LDH (rapidly progressing disease, poor prognostic factor)
- CXR, CT neck, abdomen, pelvis for staging
- PET is useful for monitoring response to treatment and evaluation of residual tumor following therapy in aggressive histological disease
- diagnosed by
  - lymph node biopsy: excisional biopsy preferred, FNA unreliable
  - bone marrow biopsy: not optimal for diagnosis as BM may not be involved

**Treatment**

- localized disease (e.g. GI, brain, bone, head and neck)
  - radiotherapy to primary site and adjacent nodal areas
  - adjuvant chemotherapy
  - surgery: splenic marginal zone lymphoma

FFP = freedom from progression at 5 yr

---

**NHL: Associated Conditions**

- Immunodeficiency (e.g. HIV)
- Autoimmune diseases (e.g. SLE)
- Infections (e.g. EBV)

---

**CHOP-Like Chemotherapy With or Without Rituximab in Young Patients with Good-Prognosis Diffuse Large B-Cell Lymphoma (MINIT)**

**Lancet Oncol** 2011;12:1013-1022

**Study**: International RCT with a median follow-up of 72 mo.

**Participants**: 824 patients with good-prognosis diffuse large B-cell lymphoma who had ≤1 risk factor, stage II-IV disease, or stage I disease with bulk (age 18-60 yr).

**Intervention**: Patients received either 6 cycles of CHOP-like chemotherapy and rituximab (CCR; n=413) or 6 cycles of CHOP-like chemotherapy alone (CLC; n=411). Bulky and extranodal sites received additional radiotherapy.

**Primary Outcome**: Event-free survival.

**Results**: Patients receiving CCR had an increased 6 yr event-free survival compared with the CLC group (74.3% vs. 55.8%; p<0.0001). Event-free survival was affected by treatment group, presence of bulky disease, and age-adjusted International Prognostic Index (IPI). Overall survival was affected by treatment group and presence of bulky disease. Within the CCR group, a favorable subgroup (IPI=0, no bulk) and less favorable subgroup (IPI=1 or bulk, or both) could be defined; event-free survival was 84.3% vs. 71.0%.

**Conclusion**: Rituximab added to six cycles of CHOP is an effective treatment for young patients with good-prognosis diffuse large B-cell lymphoma. The definition of two prognostic subgroups allows a more refined therapeutic approach to these patients than does assessment by IPI alone.
- **indolent lymphoma**: goal of treatment is symptom management
  - watchful waiting
  - radiation therapy for localized disease
  - bendamustine plus rituximab, an anti-CD20 antibody, is superior to CHOP + rituximab (CHOP-R) for advanced stage disease (StIL trial)

- **aggressive lymphoma**: goal of treatment is curative
  - combination chemotherapy: CHOP is mainstay, plus rituximab if B-cell lymphoma; different regimens for mantle cell lymphoma
  - radiation for localized/bulky disease
  - CNS prophylaxis with high-dose methotrexate if certain sites involved (testicular, nasopharyngeal)
  - relapse, resistant to therapy: high dose chemotherapy, BMT

- **highly aggressive lymphoma**
  - Burkitt lymphoma: short bursts of intensive chemotherapy
  - "CODOX-M" chemotherapy regimen also often used ± IVAC
  - CNS prophylaxis and tumor lysis syndrome prophylaxis

**Complications**
- hypersplenism
- infection
- autoimmune hemolytic anemia and thrombocytopenia
- vascular obstruction (from enlarged nodes)
- tumor lysis syndrome (particularly in very aggressive lymphoma) – see H52

**Prognosis**
- follicular lymphoma: Follicular Lymphoma International Prognostic Index is used (5 adverse prognostic factors): age >60; number of nodal areas >4; elevated LDH; Ann Arbor stage III-IV; hemoglobin <120 g/L
  - based on calculated risk, mean 5 yr survival ranges from 53-91%
  - rarely curative, typically relapsing and remitting course with risk of transformation to aggressive lymphoma such as diffuse large B-cell lymphoma
- diffuse large B-cell lymphoma: The International Prognostic Factor Index is used (5 adverse prognostic factors): age >60; Ann Arbor stage (III-IV); performance status (ECOG/Zubrand 2-4); elevated LDH; >1 extranodal site
  - based on calculated risk, mean 5 yr survival ranges from 26-73%
  - has ~40% rate of cure

Chronic Lymphocytic Leukemia

Definition
- indolent disease characterized by clonal malignancy of mature B-cells

Epidemiology
- most common leukemia in Western world
- mainly older patients; median age 65 yr
- M>F

Pathophysiology
- accumulation of neoplastic lymphocytes in blood, bone marrow, lymph nodes, and spleen

Clinical Features
- 25% asymptomatic (incidental finding)
- 5-10% present with B-symptoms (≥1 of: unintentional weight loss ≥10% of body weight within previous 6 mo, temperature >38°C or night sweats for ≥2 wk without evidence of infection, extreme fatigue)
- lymphadenopathy (50-90%), splenomegaly (25-55%), hepatomegaly (15-25%)
- immune dysregulation: autoimmune hemolytic anemia (Coombs positive), ITP, hypogammaglobulinemia ± neutropenia
- bone marrow failure: late, secondary to marrow involvement by CLL cells

Investigations
- CBC: clonal population of CLL lymphocytes >5 x 10^9/L
- peripheral blood film
  - lymphocytes are small and mature
  - smudge cells
- flow cytometry (CD5, CD20, CD23, etc.)
- cytogenetics: FISH (dictates response therapy and prognosis)
- bone marrow aspirate
  - lymphocytes >30% of all nucleated cells
  - infiltration of marrow by lymphocytes in 4 patterns: nodular (10%), interstitial (30%), diffuse (35%, worse prognosis), or mixed (25%)

Natural History and Treatment
- natural history: indolent but incurable, with slow progression; thus select gentlest treatment that will control symptoms
  - observation if early, stable, asymptomatic
  - intermittent chlorambucil or fludarabine chemotherapy combined with rituximab, chlorambucil in the elderly
  - corticosteroids, IVIg: especially for autoimmune phenomena
  - radiotherapy
- small minority present with aggressive disease; usually associated with chromosomal abnormalities (e.g. p53 deletion)
- 9 yr median survival, but varies greatly
• prognosis predicted by Rai staging
  ▪ low risk: lymphocytosis in blood and bone marrow only
  ▪ intermediate risk: lymphocytosis with enlarged nodes in any site or splenomegaly, hepatomegaly
  ▪ high risk: lymphocytosis with disease-related non-immune-mediated anemia (<11.0 g/dL) or thrombocytopenia (<100,000/mm^3)
• molecular therapies
  ▪ Idelalisib – PI3K inhibitor (not FDA-approved)
  ▪ Ibrutinib – BTK (Bruton's tyrosine kinase) inhibitor (FDA-approved in relapsed setting)

Complications
• bone marrow failure
• immune complications: AIHA, ITP, immune deficiency (hypogammaglobulinemia, impaired T-cell function)
• polyclonal or monoclonal gammopathy (often IgM)
• hyperuricemia with treatment
• 5% undergo Richter’s transformation: aggressive transformation to diffuse large B-cell lymphoma (see Table 35)

### Multiple Myeloma

#### Definition
• neoplastic clonal proliferation of plasma cells producing a monoclonal immunoglobulin resulting in end organ dysfunction
• usually single clone of plasma cells, although biclonal myeloma also occurs; rarely non-secretory

#### Epidemiology
• incidence 3 per 100,000, most common plasma cell malignancy
• increased frequency with age; median age of diagnosis is 68 yr; M>F

#### Pathophysiology
• malignant plasma cells secrete monoclonal antibody
  ▪ 95% produce M protein (monoclonal Ig = identical heavy chain + identical light chain, or light chains only)
  ▪ IgG 50%, IgA 20%, IgD 2%, IgM 0.5%
  ▪ 15-20% produce free light chains or light chains alone found in either:
    - serum as an increase in the quantity of either kappa or lambda light chain (with an abnormal kappa:lambda ratio)
    - urine has Bence-Jones protein
  ▪ <5% are non-secretory

#### Clinical Features and Complications
• bone disease: pain (usually back), bony tenderness, pathologic fractures
  ▪ lytic lesions are classical (skull, spine, proximal long bones, ribs)
  ▪ increased bone resorption secondary to osteoclast activating factors such as PTHrP
• anemia: weakness, fatigue, pallor
  ▪ secondary to bone marrow suppression
• weight loss
• infections
  ▪ usually S. pneumoniae and Gram-negatives
  ▪ secondary to suppression of normal plasma cell function
• hypercalcemia: N/V, confusion, constipation, polyuria, polydipsia
  ▪ secondary to increased bone turnover
• renal disease/renal failure
  ▪ most frequently causes cast nephropathy (see Nephrology, NP30)
• bleeding
  ▪ secondary to thrombocytopenia, may see petechiae, purpura
  ▪ can also be caused by acquired von Willebrand disease
• extramedullary plasmacytoma
  ▪ soft tissue mass composed of monoclonal plasma cells, purplish color
• hyperviscosity: may manifest as headaches, stroke, angina, MI
  ▪ secondary to increased viscosity caused by M protein
• amyloidosis
  ▪ accumulation of insoluble fibrillar protein (Ig light chain) in tissues; can cause infiltration of any organ system: cardiac infiltration – diastolic dysfunction, cardiac arrhythmias, syncope, sudden death; GI involvement – malabsorption, beefy large or laterally scalloped tongue; neurologic involvement – orthostatic hypotension, carpal tunnel syndrome
  ▪ may cause Factor X deficiency if fibrils bind Factor X → bleeding (raccoon eyes)

#### CRAB
- Increased Calcium
- Renal failure
- Anemia
- Bone lesions (lytic lesions or osteoporosis felt to be caused by myeloma)

Routine urinalysis will not detect light chains as dipstick detects albumin. Need sulfosalicylic acid or 24 h urine protein for immunofixation or electrophoresis.

### Amyloid
The general term for a variety of proteinaceous materials that have a similar structural organization and are abnormally deposited in tissues. Found in a variety of clinical disorders and can cause systemic (e.g., MM [light chains]) or localized amyloidosis (e.g., Alzheimer disease [AB amyloid]).
• neurologic disease: muscle weakness, pain, paresthesias
  ▪ radiculopathy caused by vertebral fracture, extramedullary plasmacytoma
  ▪ spinal cord compression (10-20% of patients) is a medical emergency

**Investigations**

- CBC
  ▪ normocytic anemia, thrombocytopenia, leukopenia
  ▪ rouleaux formation on peripheral film
- biochemistry
  ▪ increased Ca\(^{2+}\), increased ESR, decreased anion gap, increased Cr, albumin, \(\beta_2\)-microglobulin
  (as part of staging), proteinuria (24 h urine collection)
- monoclonal proteins
  ▪ serum protein electrophoresis (SPEP): demonstrates monoclonal protein spike in serum in 80% (i.e. M protein)
  ▪ urine protein electrophoresis (UPEP): demonstrates light chains in urine = Bence-Jones protein (15% secrete only light chains)
  ▪ immunofixation: demonstrates M protein and identifies Ig type; also identifies light chains
  ▪ serum free light chain quantification: kappa and lambda light chains, calculated ratio
- bone marrow aspirate and biopsy
  ▪ often focal abnormality, greater than 10% plasma cells, abnormal morphology, clonal plasma cells; send for FISH or cytogenetics (prognostic implications)
- skeletal series (x-rays), MRI if symptoms of cord compression
  ▪ presence of lytic lesions and areas at risk of pathologic fracture
  ▪ bone scans are not useful since they detect osteoblast activity
- \(\beta_2\)-microglobulin, LDH, and CRP are poor prognosticators

**Diagnosis**

- International Myeloma Working Group Criteria
  1. serum or urinary monoclonal protein
  2. presence of clonal plasma cells in bone marrow or a plasmacytoma
  3. presence of end-organ damage related to plasma cell dyscrasia, such as
    ▪ increased serum Ca\(^{2+}\)
    ▪ lytic bone lesions or osteoporosis
    ▪ anemia
    ▪ renal failure

**Treatment**

- treatment is non-curative
- treatment goals
  ▪ improvement in quality of life (improve anemia, reverse renal failure, bony pain)
  ▪ prevention of progression and complications
  ▪ increase overall survival
- autologous stem cell transplant as consolidation therapy
  ▪ usually preceded by 4-6 mo of cytoreductive therapy: steroid based with novel agents
    ▪ (i.e. immunomodulatory drugs or proteosome inhibitors)
  ▪ chemotherapy if >65 yr old or transplant-ineligible
    ▪ melphalan, prednisone, and novel agent (i.e. bortezomib)
  ▪ dexamethasone and bortezomib if ARF; bortezomib ± dexamethasone in light chain amyloidosis
- supportive management
  ▪ bisphosphonates for those with osteopenia or lytic bone lesions (requires renal dosing)
  ▪ local XRT for bone pain, spinal cord compression
  ▪ kyphoplasty for vertebral fractures to improve pain relief and regain height
  ▪ treat complications: hydration for hypercalcemia and renal failure, bisphosphonates for severe hypercalcemia, prophylactic antibiotics, erythropoietin for anemia, DVT prophylaxis
  ▪ all patients will relapse; choice of retreatment regimen depends on duration of remission, organ involvement, patient’s comorbidities, and preferences

**Prognosis**

- International Staging System (\(\beta_2\)-microglobulin and albumin) used to stage and estimate prognosis
  ▪ cytogenetic profile (i.e. p53 mutation associated with poor survival and resistance to chemotherapy)
  ▪ median survival based on stage, usually 16-70 mo
Monoclonal Gammopathy of Unknown Significance

**Definition**
- presence of M protein in serum in absence of any clinical or laboratory evidence of a plasma cell dyscrasia or lymphoproliferative disorders
  - incidence: 0.15% in general population, 5% of people >70 yr of age
  - asymptomatic

**Diagnosis**
- presence of a serum monoclonal protein (M protein) at a concentration <3.0 g/dL
- <10% plasma cells in bone marrow
- absence of hyperCalcemia, Renal insufficiency, Anemia, Bone disease related to the plasma cell proliferative process (absence of “CRAB”)
- 0.3-1% of patients develop a hematologic malignancy each year
  - patients with M protein peak ≥1.5 g/dL or patients with IgA or IgM MGUS are at higher risk of malignant transformation
  - patients with abnormal serum free light chains ratio are at increased risk of malignant transformation
- monitor with annual history, physical, CBC, Cr, calcium, albumin, serum protein electrophoresis (considered pre-malignant)

Lymphoplasmacytic Lymphoma (Waldenstrom’s Macroglobulinemia)

**Definition**
- proliferation of lymphoplasmacytoid cells
- presence of monoclonal IgM paraprotein

**Clinical Features**
- chronic disorder of elderly patients; median age 64 yr
- symptoms: weakness, fatigue, bleeding (oronasal), weight loss, recurrent infections, dyspnea, CHF (triad of anemia, hyperviscosity, plasma volume expansion), neurological symptoms, peripheral neuropathy, cerebral dysfunction
- signs: pallor, splenomegaly, hepatomegaly, lymphadenopathy, retinal lesions
- key complication to avoid: hyperviscosity syndrome
  - because IgM (unlike IgG) confined largely to intravascular space

**Investigations and Diagnosis**
- bone marrow shows plasmacytoid lymphocytes
- bone lesions usually not present
- blood work rarely see hypercalcemia
- cold hemagglutinin disease possible: Raynaud's phenomenon, hemolytic anemia precipitated by cold weather
- normocytic anemia, rouleaux, high ESR if hyperviscosity not present

**Management**
- R-CVP, alkylating agents (chlorambucil), nucleoside analogues (fludarabine), thalidomide, rituximab, or combination therapy
- corticosteroids
- plasmapheresis for hyperviscosity: acute reduction in serum IgM

Complications of Hematologic Malignancies

Hyperviscosity Syndrome

**Definition**
- refers to clinical sequelae of increased blood viscosity (when relative serum viscosity >5-6 units), resulting from increased circulating serum igs or from increased cellular blood components in hyperproliferative disorders (e.g. multiple myeloma, leukemia, PV)
- Waldenstrom's macroglobulinemia accounts for 85% of cases
Clinical Features
- hypervolemia causing: CHF, headache, lethargy, dilutional anemia
- CNS symptoms due to decreased cerebral blood flow: headache, vertigo, ataxia, stroke
- retina shows venous engorgement and hemorrhages
- bleeding diathesis
  - due to impaired platelet function, absorption of soluble coagulation factors (e.g. nasal bleeding, oozing gums)
- ESR usually very low

Treatment
- plasmapheresis, chemotherapy

Tumor Lysis Syndrome

Definition
- group of metabolic complications that result from spontaneous or treatment-related breakdown of cancer cells
- more common in diseases with large tumor burden and high proliferative rate (high grade lymphoma, leukemia)

Clinical Features
- metabolic abnormalities
  - cells lyse, releasing K⁺, uric acid, PO₄³⁻ (increased levels)
  - PO₄³⁻ binds Ca²⁺ (decreased Ca²⁺)
- complications
  - lethal cardiac arrhythmia (increased K⁺)
  - acute renal failure (urate nephropathy, see Nephrology, NP30)

Treatment
- prevention
  - aggressive IV hydration
  - alkalization of the urine
  - allopurinol or rasburicase
  - correction of pre-existing metabolic abnormalities
- dialysis

Blood Products and Transfusions

Blood Products
- RBCs, platelets and coagulation factors (frozen plasma [FP], cryoprecipitate, factor concentrates) are available for transfusion
- donated blood (1 U = 450-500 mL) is fractionated into these various components
  - centrifugation separates whole blood into RBCs and platelet-rich plasma
  - platelet-rich plasma is further fractionated into platelets and plasma
    - need to pool together multiple units to obtain therapeutic amounts
    - FP (previously known as FFP) is plasma frozen within 24 h of collection
    - cryoprecipitate is the high MW precipitate generated when FP is thawed at low temperatures

Specialized Products
- irradiated blood products
  - prevent proliferation of donor T-cells in potential or actual BMT recipients
  - used for immunocompromised patients or for patients on purine analogue chemotherapy, first-degree relatives, HLA-matched products and intrauterine transfusions, Hodgkin lymphoma
- CMV-negative blood products
  - potential transplant recipients
  - neonates
  - AIDS patients
  - seronegative pregnant women

**Red Blood Cells**

**Packed Red Blood Cells**
- stored at 4°C
- transfuse within 42 d of collection, otherwise cell lysis may result in hyperkalemia
- infuse each unit over 2 h, max of 4 h

**Indications for packed RBC Transfusion**
- Hb <7.0 g/dL; this may change as per patient’s tolerance or symptoms
  - maintain Hb between 7.0 and 10.0 g/dL during active bleeds
- consider maintaining a higher Hb for patients with:
  - CAD/unstable coronary syndromes
  - uncontrolled, unpredictable bleeding
  - impaired pulmonary function
  - increased O₂ consumption

**Selection of Red Cells for Transfusion**
- when a need for RBC transfusion is anticipated, the following should be ordered
  - group and screen: determines the blood group and Rh status of the recipient as well as the presence of autoantibodies vs. major/minor blood group antigens in the patient’s serum
  - crossmatch: involves mixing the recipient’s blood with potential donor blood and looking for agglutination (takes 30–45 min)
- when blood is required, several options are available
  - 1st line: fully crossmatched blood, electronic crossmatch is becoming more widely used (not always available in emergency situations)
  - 2nd line: donor blood of the same group and Rh status as the recipient
  - 3rd line: O- blood for females of reproductive age; O+ blood for all others

**Platelets**

**Table 37. Platelet Products**

<tr>
<td>Single donor platelets</td>
<td>Potential BMT recipients</td>
</tr>
<tr>
<td>HLA matched platelets</td>
<td>Refractory to pooled or single donor platelets, presence of HLA antibodies</td>
</tr>
</tbody>
</table>

- stored at 20-24°C
- random donor platelets are transfused from a pool of 4 units; this should increase the platelet count by ≥15,000/mm³
- single donor platelets (transfused as single units) should increase the platelet count by 40-60,000/mm³
- if an increase in the platelet count is not seen post-transfusion: autoantibodies (i.e. ITP), alloantibodies, consumption (bleeding, sepsis), or hypersplenism may be present

**Relative Contraindications of Platelet Transfusion**
- TTP, HIT, post-transfusion purpura, HELLP

---

1 unit of pRBC will increase Hb by approximately 10 g/L or increase Hct by 4%.

American Society of Hematology
Choosing Wisely Recommendation
Do not transfuse more than the minimum number of RBC units necessary to relieve symptoms of anemia or to return the patient to a safe hemoglobin range (70-80 g/L) in stable noncardiac patients.

Transfusion Requirements in Critical Care (TRICC)
NEJM 1999;340:409-417
Study: Multicenter, RCT.
Participants: 839 critically ill patients with euolemia after initial treatment and hemoglobin less than 9 g/dL within 72 h of ICU admission.
Intervention: Patients receiving a transfusion followed either (1) a restrictive strategy (RS, n=418) in which red cells were transfused if hemoglobin was less than 7.0 g/dL and then maintained at 7.9 g/dL or (2) a liberal strategy (LS, n=420) in which transfusions occurred when the hemoglobin was less than 10.0 g/dL and then maintained at 10-12 g/L.
Primary Outcome: Mortality at 30 d and severity of organ dysfunction.
Results: Mortality rates at 30 d were similar between groups. However, mortality rates were significantly lower with the RS among less acutely ill patients (6.7% RS and 16.1% LS group; p=0.03) and among those less than 53 yr of age (5.7% RS and 13% LS; p=0.02), but did not differ in a subgroup with clinically significant cardiac disease.
Conclusion: A RS of red cell transfusion is at least as effective as, and possibly superior to, a LS transfusion in critically ill patients.

Liberal or Restrictive Transfusion in High-Risk Patients After Hip Surgery (FOCUS)
NEJM 2011;365:2453-2462
Study: Multicenter RCT.
Participants: 2,016 patients aged >50 yr with a history of or risk factors for cardiovascular disease and hemoglobin (Hb) level below 10 g/dL after hip fracture surgery.
Intervention: Patients were randomly assigned to a liberal transfusion strategy (a Hb threshold of 10 g/dL) or a restrictive transfusion strategy (anemia symptoms or at physician discretion for a Hb level less than 8 g/dL).
Primary Outcome: Mortality or inability to walk across a room without human assistance on a 60 day follow-up.
Results: Primary outcome rates were 35.2% in the liberal transfusion strategy group and 34.7% in the restrictive transfusion strategy group. Rates of complications were similar in the two groups.
Conclusion: A liberal transfusion strategy did not reduce mortality rates or the inability to walk independently on 60 day follow-up compared to a restrictive transfusion strategy in elderly patients with high cardiovascular risk factors after hip surgery.

Acute Blood Transfusion Reactions

IMMUNE

Acute Hemolytic Transfusion Reactions
- ABO incompatibility resulting in intravascular hemolysis secondary to complement activation, occurs immediately after transfusion
- most commonly due to incorrect patient identification
- risk per unit of blood is <1 in 40,000
- presentation: fever, chills, hypotension, back or flank pain, dyspnea, hemoglobinuria
- acute renal failure (<24 h) and DIC
- treatment
  - stop transfusion
  - notify blood bank and check for clerical error
  - maintain BP with vigorous IV fluids ± inotropes
  - maintain urine output with diuretics, crystalloids, dopamine

Febrile Nonhemolytic Transfusion Reactions
- due to alloantibodies to WBC, platelets or other donor plasma antigens and release of cytokines from blood product cells
- occurs within 0-6 h of transfusion
- risk per unit of blood is 1 in 100 (minor), 1 in 10,000 to 40,000 (severe)
- presents with fever ± rigors, facial flushing, headache, myalgia, hypotension
- treatment
  - rule out hemolytic reaction or infection
  - if temperature <38°C, continue with transfusion but decrease rate and give antipyretics
  - if temperature >38°C, stop transfusion, give antipyretics and anti-histamine

Allergic Nonhemolytic Transfusion Reactions
- alloantibodies (IgE) to proteins in donor plasma result in mast cell activation and release of histamine
- occurs mainly in those with history of multiple transfusions or multiparous women
- risk per unit of blood is 1 in 100
- presents mainly as urticaria and occasionally with fever
- can present as anaphylactoid reaction with bronchospasm, laryngeal edema, and hypotension, but this occurs mainly in IgA deficient patients that have anti-IgA antibodies
- treatment
  - mild: slow transfusion rate and give diphenhydramine
  - moderate to severe: stop transfusion, give IV diphenhydramine, steroids, epinephrine, IV fluids, and bronchodilators

Transfusion-Related Acute Lung Injury
- new-onset acute lung injury that occurs during transfusion or within 6 h of transfusion completion
  - insidious, acute onset of pulmonary insufficiency
  - profound hypoxemia (PaO2/FiO2 <300 mmHg)
  - bilateral pulmonary edema on CXR
  - pulmonary artery wedge pressure <18 mmHg
  - no clinical evidence of left atrial HTN
- pathogenesis uncertain; perhaps due to binding of donor antibodies to WBC of recipient and release of mediators that increase capillary permeability in the lungs
- typically occurs 2-4 h post transfusion and resolves in 24-72 h
- risk per unit of blood is 1:10,000
  - is currently the leading cause of transfusion-related morbidity and mortality
- treatment: supportive therapy (oxygen)
  - inform blood bank; patient and donor testing will be arranged

DDx of Post-Transfusion Fever
- Acute hemolytic transfusion reaction
- Febrile non-hemolytic transfusion reaction
- Bacterial contamination
- Allergy

DDx of Post-Transfusion Dyspnea
- Transfusion-associated circulatory overload (TACO)
- Transfusion-related acute lung injury (TRALI)
- Allergy (bronchospasm/anaphylaxis)
NONIMMUNE

Transfusion-Associated Circulatory Overload
- due to impaired cardiac function and/or excessive rapid transfusion
- presentation: dyspnea, orthopnea, hypotension, tachycardia, crackles at base of lung, and increased venous pressure
- incidence: 1 in 700 and is becoming more common
- treatment: transfuse at lower rate, give diuretics and oxygen

Bacterial Infection
- Gram positive: S. aureus, S. epidermidis, Bacillus cereus
- Gram negative: Klebsiella, Serratia, Pseudomonas, Yersinia
- overall risk is 1 in 100,000 for RBC and 1 in 10,000 for platelets
- never store blood >4 h after bag has left blood bank
- treatment: stop transfusion, blood cultures, IV antibiotics, fluids

Hyperkalemia
- due to K+ release from stored RBC
- risk increases with storage time and if blood is irradiated and risk decreases
- if given fresh blood
- occurs in 5% of massively transfused patients
- treatment: see Nephrology, NP13

Citrate Toxicity
- occurs with massive transfusion in patients with liver disease – patients are unable to clear citrate from blood
- citrate binds to Ca2+ and causes signs and symptoms of hypocalcemia
- treatment: IV calcium gluconate (10 mL of 10%) for every 2 units of blood

Dilutional Coagulopathy
- occurs with massive transfusion (>10 units)
- pRBC contains no clotting factors, fibrinogen, cryoprecipitate, or platelets
- treatment: FP, platelets, and cryoprecipitate

Delayed Blood Transfusion Reactions

IMMUNE

Delayed Hemolytic
- due to alloantibodies to minor antigens such as Rh, Kell, Duffy, Kidd, and MNS
- titre of antibody at time of transfusion is too low to cause hemolysis; later the level of antibody increases due to secondary stimulus and causes extravascular hemolysis
- occurs 5-7 d after transfusion
- presentation: anemia and mild jaundice
- treatment: no specific treatment required; important to note for future transfusion

Transfusion-Associated Graft Vs. Host Disease
- transfused T-lymphocytes recognize and react against “host” (recipient)
- occurs 4-30 d following transfusion
- most patients already have severely impaired immune systems (e.g. Hodgkin lymphoma or leukemia)
- may occur in immunocompetent individuals in setting of a designated transfusion from a related donor (decreased incidence with irradiated blood)
- presentation: fever, diarrhea, liver function abnormalities, and pancytopenia
- can be prevented by giving irradiated blood products

NONIMMUNE

Iron Overload
- due to repeated transfusions over long period of time (e.g. β-thalassemia major)
- can cause secondary hemochromatosis
- treatment: iron chelators or phlebotomy if not longer requiring blood transfusion and not anemic

Viral Infection Risk
- HBV <1 in 153,000
- Human T-lymphotropic virus (HTLV) <1 in 4,300,000
- HCV <1 in 2,300,000
- HIV <1 in 7,000,000
- other infections include EBV, CMV, WNV (West Nile virus)
Common Medications

Antiplatelet Therapy

- see Figure 11a, Platelet Activation Cascade, H26

<td>Contraindicated in renal failure, cancer patients, mechanical heart valves</td>
</tr>
</tbody>
</table>

Contraindications:
- LMWH: Contraindicated in renal failure, pregnancy, placenta (teratogenic)
- Dabigatran: Contraindicated in renal failure, cancer patients, mechanical heart valves

Adverse Reactions of Heparin
- hemorrhage: depends on dose, age, and concomitant use of antiplatelet agents or thrombolytics
- heparin-induced thrombocytopenia: associated with venous or arterial thrombosis (see Table 23, H29)
- osteoporosis: with long-term use

Low Molecular Weight Heparin (enoxaparin, dalteparin, tinzaparin)
- increased bioavailability compared to normal heparin
- increased duration of action
- SC route of administration
- do not need to monitor aPTT
- adverse reactions less common than UFH
- patients with renal failure (CrCl <30) can accumulate LMWH, therefore must adjust dose
- only partially reversible with protamine sulphate

Bacteriology

**Bacteria Basics**
- bacteria are prokaryotic cells that divide asexually by binary fission
- Gram stain divides most bacteria into two groups based on their cell wall
  - Gram positive (GP): thick, rigid layer of peptidoglycan
  - Gram negative (GN): thin peptidoglycan layer + thicker outer membrane composed of lipoproteins and lipopolysaccharides
  - clinical significance: GN thick outer membrane makes it resistant to penicillin's mechanism of action
- AFB: high myclic acid content in cell wall, "acid fast" as washout phase of Gram stain is ineffective, e.g. *Mycobacteria, Nocardia*
- "atypical" bacteria: not seen on Gram stain and difficult to culture
  - obligate intracellular bacteria: e.g. *Mycoplasma*
  - spirochetes: e.g. *Treponema pallidum*
- *O₂* can be either vital or detrimental to growth
  - obligate aerobes: require *O₂*
  - obligate anaerobes: require environment without *O₂*
  - facultative anaerobes: can survive in environments with or without *O₂*

**Mechanisms of Bacterial Disease**
1. adherence to and colonization of skin or mucous membranes
   - e.g. fimbrilation (pill) microfilaments extending through the cell wall – like burrs sticking to your clothes, they attach to epithelial cells e.g. *E. coli* in the urinary tract
2. invasion or crossing normal epithelial barriers
   - evasion of host defense system through inhibition of:
     - phagocytic uptake via polysaccharide capsule (*S. pneumoniae, N. meningitidis, H. influenzae*)
     - or surface proteins (*Staphylococcus, Streptococcus*)
3. toxin production
   - exotoxins are secreted by living pathogenic bacteria and cause disease even if the bacteria is not present (e.g. *Clostridium*)
   - endotoxins are structural components of GN bacterial cell wall, and may be shed by live cells or released during cell lysis
4. intracellular growth
   - obligate intracellular: *Rickettsia* and *Chlamydia*
   - facultative intracellular: *Salmonella, Neisseria, Brucella, Mycobacteria, Listeria, Legionella*
5. biofilm
   - an extracellular polysaccharide network forming mesh around the bacteria (e.g. *S. epidermidis*) which can coat prosthetic devices like IV catheters

Figure 2. Laboratory identification of bacterial species
# Virology

## Viral Basics
- Viruses are infectious particles consisting of RNA or DNA covered by a protein coat
  - Infect cells and use host metabolic machinery to replicate
  - Nucleic acid can be double stranded (ds) or single stranded (ss)
  - Can be enveloped or naked
- Virions are mature virus particles that can be released into the extracellular environment
- Host susceptibility is governed by the host cell and virus surface proteins (viral tropism) and cellular immunity

## Viral Disease Patterns
1. Acute infections (e.g. adenovirus)
   - Host cells are lysed in the process of virion release
   - Some produce acute infections with late sequelae (e.g. measles virus → subacute sclerosing panencephalitis)
2. Chronic infections (>6 mo): (e.g. HBV, HIV)
   - Host cell machinery is used to produce and chronically release virions
3. Latent infections
   - Viral genome remains latent in host cell nucleus
   - Can reactivate (e.g. HSV, VZV)

Figure 3. Virus morphology
Mycology

Fungal Basics
- fungi are eukaryotic organisms, they can have the following morphologies
  1. yeast (unicellular)
  2. molds (also known as filamentous fungi) (multicellular with hyphae)
  3. dimorphic fungi (found as mold at room temperature but grow as yeast-like forms at body temperature)

Table 4. Membrane and Cell Wall Compositions

<tr>
<td>Bacteria</td>
<td>Peptidoglycan</td>
</tr>
<tr>
<td>Human Cell</td>
<td>Cholesterol</td>
</tr>
<tr>
<td>Fungi</td>
<td>Ergosterol, Chitin</td>
</tr>
</tbody>
</table>

Mechanisms of Fungal Disease
- primary fungal infection by
  - overgrowth of normal flora (e.g. Candida species)
  - inhalation of fungal spores
  - traumatic inoculation into skin
- toxins produced by fungi (e.g. ingestion aflatoxins)
- allergic reactions to fungi (e.g. bronchopulmonary aspergillosis)

Parasitology

Parasite Basics
- parasite: an organism that lives in or on another organism (host) and damages the host in the process
- parasites with complex life cycles require more than one host to reproduce
  - reservoir host: maintains a parasite and may be the source for human infection
  - intermediate host: maintains the asexual stage of a parasite or allows development of the parasite to proceed to the larval stage
  - definitive host: allows the parasite to develop to the adult stage where reproduction occurs
- 2 major groups of parasites: protozoa and helminths
- see Tables 26 and 27 for examples of clinically important parasites

Table 5. Differences Between Protozoa and Helminths

<table>
<thead>
<tr>
<th>Protozoa</th>
<th>Helminths</th>

<td>Eosinophilia (proportional to extent of tissue invasion)*</td>
</tr>
<tr>
<td>Indefinite life span</td>
<td>Definite life span</td>
</tr>
</tbody>
</table>

*Adult ascari (roundworm) does not cause eosinophilia

Characteristics of Parasitic Disease
- symptoms are usually proportional to parasite burden
- tissue damage is due to the parasite and host immune response
- chronic infections may occur with or without overt disease
- immunocompromised hosts are more susceptible to manifestations of infection, reactivation of latent infections, and more severe disease
- eosinophilia may suggest a parasitic infection

Mechanisms of Parasitic Disease
1. mechanical obstruction (e.g. ascariasis, clonorchiasis)
2. competition with host for resources (e.g. anemia in hookworm disease, vitamin B12 deficiency in diphyllobothriasis)
3. cytotoxicity leading to abscesses and ulcers (e.g. amoebiasis, leishmaniasis)
4. inflammatory
  - acute hypersensitivity (e.g. pneumonitis in Loeffler’s syndrome)
  - delayed hypersensitivity (e.g. egg granulomas in schistosomiasis)
  - cytokine-mediated (systemic illness of malaria, disseminated strongyloidiasis)
5. immune-mediated injury
  - autoimmune (e.g. myocarditis of Chagas disease, tissue destruction of mucocutaneous leishmaniasis)
  - immune complex (e.g. nephritis of malaria, schistosomiasis)
Transmission of Infectious Diseases

<table>

*see Prevention of Infectious Diseases for further detail

Prevention of Infectious Diseases

Overview
- efforts to control the spread of infectious disease involves infection control and prevention measures in health care settings and public health measures outside of health care settings

Infection Control and Prevention Measures
1. surveillance for important nosocomial infections or problem organisms (such as: surgical site infections, vascular access-related infections, C. difficile infections, colonization or infections due to antimicrobial resistant organisms e.g. methicillin-resistant S. aureus). (see Population and Community Health, PH19 for a definition of active vs. passive surveillance)
2. routine practices (also known as standard precautions) used for all patients
   - perform hand hygiene before and after seeing patient or patient environment contact, before aseptic procedures, and after body fluid exposure
   - use gloves for any encounter with body fluids
   - wear eye protection, mask, and gown for any procedures likely to generate splashes of body fluids
   - do not recap sharps by hand and dispose of sharps in puncture-resistant container near point-of-use
   - use mouthpieces for resuscitator bags instead of using mouth-to-mouth resuscitation
   - discard soiled waste properly
3. additional precautions used for various syndromes or known infectious diseases
   - contact precautions (private room, gown, gloves to be used routinely) (e.g. used for patients with C. difficile)
   - droplet/contact precautions (private room, gown, gloves, eye protection, fluid-resistant mask) (e.g. used for influenza, meningitis due to Neisseria meningitidis)
   - airborne precautions (negative-pressure private room with door closed, fit-tested N95 respirator) (e.g. used for TB, measles, VZV)

Study: RCT stopped after an interim analysis.
Population: 43 patients at least 18 yr of age, with a life expectancy of at least 3 mo, and a relapse of C. difficile after at least one course of adequate antibiotic therapy (≥10 d of vancomycin at a dose of ≥125 mg q6h or ≥10 d of metronidazole at a dose of 500 mg q8h).
Primary Outcome: Resolution of diarrhea associated with C. difficile infection without relapse after 10 wk.
Results: 87% of patients in the group with duodenal infusion of donor feces had a resolution of C. difficile-associated diarrhea after the first infusion. 31% of patients receiving vancomycin with bowel lavage had a resolution of C difficile-associated diarrhea. After the infusion, patients showed greater fecal bacterial diversity similar to healthy donors.
Conclusions: Infusion of donor feces was more effective for the treatment of recurrent C. difficile infection than the use of vancomycin alone or vancomycin with bowel lavage.
4. decolonization (e.g. topical and oral antimicrobials be used in an attempt to decolonize methicillin-resistant S. aureus [MRSA])
5. outbreak investigations (see Population and Community Health, PH19)

Public Health Measures
1. vaccination
2. post-exposure prophylaxis (e.g. use of immunoglobulin or vaccination post-exposure to infectious disease agents in an attempt to reduce the likelihood or severity of disease)
3. reportable diseases (e.g. list of reportable communicable diseases that physicians are legally required to report to local public health officials) (see Population and Community Health, PH25)
4. contact tracing (tracking of individuals who have been exposed to a person with a communicable disease during its period of communicability)
5. quarantine (restriction of the activities or well persons who have been exposed to a person with a communicable disease during its period of communicability to prevent disease transmission during the incubation period if infection should occur)
6. outbreak investigation (see Population and Community Health, PH19)

Nosocomial Infections

- definition: infections acquired >48 h after admission to a healthcare facility or within 30 d from discharge
- risk factors: prolonged hospital stay, antibiotic use, surgery, hemodialysis, intensive care, colonization with a resistant organism, immunodeficiency
- patients with nosocomial infections have higher mortality, longer hospital stays, and higher healthcare costs
- hand hygiene is an essential precaution

Table 7. Common Nosocomial Infectious Agents

</table>
Pneumonia

• see Pediatrics, P90
• see Family Medicine, FM18

Definition
• infection of the lung parenchyma

Etiology and Risk Factors
• impaired lung defenses
  ▪ poor cough/gag reflex (e.g. illness, drug-induced)
  ▪ impaired mucociliary transport (e.g. smoking, cystic fibrosis)
  ▪ immunosuppression (e.g. steroids, chemotherapy, AIDS/HIV, DM, transplant, cancer)
• increased risk of aspiration
  ▪ impaired swallowing mechanism (e.g. impaired consciousness, neurologic illness causing dysphagia, mechanical obstruction)
• no organism identified in 75% of hospitalized cases, and >90% of ambulatory cases

*See Pediatrics P90, Table 45 for Common Causes and Treatment of Pneumonia at Different Ages

Clinical Features
• cough (+ sputum), fever, pleuritic chest pain, dyspnea, tachypnea, tachycardia
• elderly often present atypically; altered LOC is sometimes the only sign
• evidence of consolidation (dullness to percussion, bronchial breath sounds, crackles)
• features of parapneumonic effusion (decreased air entry, dullness to percussion) (see Respirology, R21)
• complications: ARDS, lung abscess, parapneumonic effusion/empyema, pleuritis ± hemorrhage

Investigations
• pulse oximetry to assess severity of respiratory distress
• CBC and differential, electrolytes, urea, Cr, ABG (if respiratory distress), troponin/CK, LFTs, urinalysis
• sputum Gram stain/C&S, blood C&S, ± serology/viral detection, ± pleural fluid C&S (if effusion >5 cm or respiratory distress)
• CXR±CT chest shows distribution (lobar consolidation or interstitial pattern), extent of infiltrate ± cavitation
• bronchoscopy ± washings for:
  ▪ (1) severely ill patients refractory to treatment or (2) immunocompromised patients

Treatment
• ABC, O2, IV fluids, consider salbutamol (nebulized or MDI)
• determine prognosis and need for hospitalization and antibiotics

When Klebsiella causes pneumonia; see red currant jelly sputum

Aspiration pneumonias more commonly manifest as infiltrates in the right middle or lower lobes due to the larger caliber and more vertical orientation of the right bronchus

Note: Always use directed therapy against specific organism if one is found on culture (e.g. blood, sputum, etc.)

Prevention

- Vaccine for influenza A and B recommended annually for all ages
- Two pneumococcal polysaccharide vaccines available: 23 valent (indicated for all adults) and 13 valent (indicated for adults >50 yr)
- The CDC recommends giving Prevnar-13® to all adults at high risk for invasive pneumococcal disease (>65 yr, 19-64 with chronic disease, smokers, residents of long-term care facilities, Aboriginal peoples 50-64 yr)
### Influenza

**Definitions and Etiology**
- influenza viruses A and B
- influenza A further divided into subtypes based on envelope glycoproteins:
  - hemagglutinin (H) and neuraminidase (N)
- seasonal (epidemic) influenza
  - main circulating influenza viruses: human-origin A (H1N1) and B (H3N2) subtypes
  - associated with antigenic drift (gradual, minor changes due to random point mutations)
  - may create a new viral subtype resulting in a seasonal epidemic (disease prevalence is greater than expected)
  - outbreaks occur mainly during winter months (late December to early March)
- pandemic influenza
  - associated with antigenic shift: abrupt, major changes due to mixing of two different viral strains from different hosts
  - may create a new viral strain resulting in a pandemic outbreak (worldwide)
  - antigenic shift occurs only in type A
- transmission: droplet, possibly airborne

| Table 12. Difference Between Influenza Strains |
|-----------------|-----------------|
|                | Influenza A     | Influenza B     |
| Host(s)        | Humans, birds, mammals | Humans only |
| Antigenic drift| Yes, new strains | Yes, new strains |
| Antigenic shift | Yes, new subtypes | No |
| Epidemics      | Yes             | Yes             |
| Pandemics      | Yes             | No              |

**Clinical Features**
- incubation period 1-4 d
- acute onset of systemic (fever, chills, myalgias, arthralgias, headache, fatigue) and respiratory symptoms (cough, dyspnea, pharyngitis)
- complications: respiratory (viral pneumonia, secondary bacterial pneumonia, otitis media, sinusitis), muscular (rhabdomyolysis, myositis), neurologic (encephalitis, meningitis, transverse myelitis, Guillain-Barré syndrome)

**Investigations**
- diagnosis is primarily clinical based on symptoms during the influenza season
- nasopharyngeal swabs for rapid antigen detection, DFA (Direct Fluorescent Antigen) detection, RT-PCR (gold standard)
- serology: rarely used for clinical management

**Treatment and Prevention**
- primarily supportive unless severe infection or high-risk of complications (e.g. elderly, pulmonary or cardiac disease)
- neuraminidase inhibitors: zanamivir (Relenza*) and oseltamivir (Tamiflu*) for treatment and prophylaxis against types A and B
  - decreases duration (by 1-2 d) and severity of symptoms if given within <48 h of onset
  - treatment beyond 48 h time window may be warranted in immunosuppressed and critically ill patients
- M2-inhibitors: amantidine/rimantidine for treatment and prophylaxis against type A only no longer recommended due to increased resistance
- vaccine for influenza A and B viruses is recommended annually for all ages
  - vaccine is reformulated each year to reflect circulating influenza A and B strains

### Cellulitis

**Definition**
- acute infection of the skin principally involving the dermis and subcutaneous tissue

**Etiology**
- common causative agents: S. aureus, β-hemolytic streptococci
- immunocompromised patients or water exposure: may also include GN rods and fungi
- risk factors:
  - trauma with direct inoculation, recent surgery
  - peripheral vascular disease, lymphedema diabetes, cracked skin in feet/toes (tinea pedis)

---

*Vaccines for Preventing Influenza in Healthy Adults*

*Cochrane DB Syst Rev 2014;CD001269*

**Study:** Meta-analysis of 90 RCTs and quasi-RCTs evaluating influenza vaccines compared to placebo in healthy individuals aged 16-65 yr.

**Results:** The preventative effect of inactivated influenza vaccine on healthy adults is small: 40 people would need a vaccination to avoid one influenza-like illness and 71 people would need a vaccination to prevent one case of influenza. 15.6% of unvaccinated vs. 9.9% of vaccinated people developed influenza-like symptoms: of these participants, only 2.4% and 1.1%, respectively, developed laboratory-confirmed influenza. Vaccination had a modest effect on working days lost, but no effects on hospitalization or complications. The effectiveness of live aerosol vaccinations on healthy adults is similar to that of inactivated influenza vaccines: 46 people would need a vaccination to avoid one influenza-like illness.

**Conclusions:** Influenza vaccines have a very modest effect in reducing influenza-like illness and working days lost in the general population.
Clinical Features
• pain, edema, erythema with indistinct borders ± regional lymphadenopathy, systemic symptoms (fevers, chills, malaise)
• can lead to ascending lymphangitis (visible red streaking in skin along lymphatics proximal to area of cellulitis)

Investigations
• CBC and differential, blood C&S if febrile
• skin swab ONLY if open wound with pus

Treatment
• antibiotics: cephalaxin (broader coverage if risk factors for GN rods)
• if extensive erythema or systemic symptoms, consider cefazolin IV
• limb rest and elevation may help reduce swelling

Necrotizing Fasciitis

Definition
• life- and limb-threatening infection of the deep fascia characterized by rapid spread

Etiology
• Two main forms
  ▪ Type I: polymicrobial infection – aerobes and anaerobes (e.g. S. aureus, Bacteroides, Enterobacteriaceae)
  ▪ Type II: monomicrobial infection with GAS

Clinical Features
• pain out of proportion to clinical findings and beyond border of erythema
• edema, ± crepitus (subcutaneous gas from anaerobes), ± fever
• infection spreads rapidly
• patients may rapidly become very sick (tachycardia, hypotension, lightheadedness)
• late findings
  ▪ skin turns dusky blue and black (secondary to thrombosis and necrosis)
  ▪ induration, formation of hemorrhagic bullae

Investigations
• a clinical/surgical diagnosis – do NOT wait for results of investigations before beginning treatment
• blood and tissue C&S
• serum CK (elevated CK usually means myonecrosis – a late sign)
• plain film x-ray (soft tissue gas may be visualized)
• surgical exploration for debridement of infected tissue

Treatment
• resuscitation with IV fluids
• emergency surgical debrideaments to confirm diagnosis and remove necrotic tissue (may require amputation)
• IV antibiotics
  ▪ unknown organism: meropenem or piperacillin/tazobactam + clindamycin IV ± vancomycin if MRSA is considered
  ▪ Type I (polymicrobial): piperacillin/tazobactam + clindamycin IV
  ▪ Type II (monomicrobial): penicillin G + clindamycin IV
  ▪ with Type II, evaluate for streptococcal toxic shock syndrome and the need for IVIg

Gastrointestinal Infections

Acute Diarrhea
• see Gastroenterology, G15
• see Pediatrics, P35
• see Family Medicine, FM26

Epidemiology
• one of the top five leading causes of death worldwide, according to the World Health Organization
• significant morbidity in developed countries (over 900,000 hospitalizations in United States each year)
Definition
• passage of ≥3 loose or liquid stools/d OR >200 g stool/d for >2 d but ≤14 d

Approach to Acute Diarrhea
• rationale
  ▪ the vast majority of acute diarrhea is caused by infection
  ▪ in most cases, acute diarrheal illness is viral and/or self-limited, and lasts <3 d
  ▪ investigations are costly and are necessary only in certain circumstances
• therefore, the evaluation of acute diarrhea involves:
  ▪ identifying characteristics of the illness or patient that warrant further investigation
  ▪ assessing volume status to determine appropriate method of rehydration
• see Figure 7

Physical Exam
• volume status: appearance, level of alertness, pulse, BP, orthostatic vitals, JVP, mucous membranes, skin turgor, capillary refill
• abdominal exam: pain, guarding, peritoneal signs

Treatment
• rehydration is mainstay of treatment
  ▪ oral rehydration therapy
  ▪ IV rehydration if oral intake insufficient to replace fluid loss
• antidiarrheal agents reduce duration of diarrhea: loperamide, bismuth salicylate
  ▪ delays excretion of causative pathogens
  ▪ contraindications: diarrhea with fever, bloody stool or diarrhea caused by Clostridium difficile
• antibiotic therapy is rarely indicated because:
  ▪ most acute diarrheal illness is viral and self-limited
  ▪ antibiotics can eradicate normal gut flora, predisposing patient to C. difficile infection
  ▪ antibiotics prolong the shedding of Salmonella and other causes of bacterial diarrhea
  ▪ in EHEC infection, antibiotics may increase the risk of HUS
  ▪ indications for antibiotic therapy are shown in Figure 7

Figure 7. Approach to acute diarrhea

**Traveler’s Diarrhea**

- see *Acute Diarrhea*, ID11

**Epidemiology**
- the most common illness to affect travelers
- up to 50% of travelers to developing countries affected in first 2 wk and 10-20% after returning home

**Etiology**
- bacterial (80-90%): *E. coli* most common (ETEC), *Campylobacter, Shigella, Salmonella, Vibrio* (non-cholera); wide regional variation (e.g. *Campylobacter* more common in Southeast Asia)
- viral: norovirus, rotavirus, and astrovirus account for 5-8%
- protozoal (rarely): *Giardia, Entamoeba histolytica, Cryptosporidium, Cyclospora* for ~10% in long-term travelers
- pathogen-negative traveler’s diarrhea common despite exhaustive microbiological workup

**Treatment**
- rehydration is the mainstay of therapy
  - rehydrate with sealed beverages
  - in severe fluid loss use oral rehydration solutions (1 package in 1 L boiled or treated water)
  - treat symptoms: antidiarrheal agents (e.g. bismuth salicylate, loperamide)
  - empiric antibiotics in moderate or severe illness: ciprofloxacin or azithromycin or rifaximin
- note: there is increasing fluoroquinolone resistance in causative agents, especially in Southeast Asia

**Prevention**
- proper hygiene practices
  - avoid consumption of: foods or beverages from establishments with unhygienic conditions (e.g. street vendors), raw fruits or vegetables without a peel, raw or undercooked meat and seafood
  - avoid untreated water
  - bismuth salicylate (Pepto-Bismol®): 60% effective (2 tablets qid according to CDC website)
- CDC Guidelines: antibiotic prophylaxis not recommended
  - increased risk of infection with resistant organisms
- high risk groups (e.g. immunocompromised) likely to be infected with pathogen not covered by standard antimicrobial agents
- Dukoral®: oral vaccine that offers protection against *V. cholerae* (efficacy ~80%) and ETEC (efficacy ~50-67%); the CDC does not recommend it for routine use in travelers

### Chronic Diarrhea

- see [*Gastroenterology*, G16]

### Peptic Ulcer Disease (*H. pylori*)
